- - - - - - - - - - - - - - - - - - - - - - -

 **Model Is Setup For Calculation of Average CONCentration Values.

   --  DEPOSITION LOGIC  --
 **NO GAS DEPOSITION Data Provided.
 **NO PARTICLE DEPOSITION Data Provided.
 **Model Uses NO DRY DEPLETION.  DRYDPLT  =  F
 **Model Uses NO WET DEPLETION.  WETDPLT  =  F

 **Model Uses RURAL Dispersion Only.

 **Model Uses Regulatory DEFAULT Options:
        1. Stack-tip Downwash.
        2. Model Accounts for ELEVated Terrain Effects.
        3. Use Calms Processing Routine.
        4. Use Missing Data Processing Routine.
        5. No Exponential Decay.

 **Other Options Specified:
        CCVR_Sub - Meteorological data includes CCVR substitutions
        TEMP_Sub - Meteorological data includes TEMP substitutions

 **Model Assumes No FLAGPOLE Receptor Heights.

 **The User Specified a Pollutant Type of:  PM_2.5

 **Model Calculates  1 Short Term Average(s) of:   1-HR
     and Calculates ANNUAL Averages

 **This Run Includes:      1 Source(s);       1 Source Group(s); and     841
Receptor(s)

                with:      0 POINT(s), including
                           0 POINTCAP(s) and      0 POINTHOR(s)
                 and:      0 VOLUME source(s)
                 and:      1 AREA type source(s)
                 and:      0 LINE source(s)
                 and:      0 OPENPIT source(s)
                 and:      0 BUOYANT LINE source(s) with      0 line(s)

 **Model Set To Continue RUNning After the Setup Testing.

 **The AERMET Input Meteorological Data Version Date:  14134

 **Output Options Selected:
         Model Outputs Tables of ANNUAL Averages by Receptor
```

Model Outputs Tables of Highest Short Term Values by Receptor (RECTABLE Keyword)
Model Outputs External File(s) of High Values for Plotting (PLOTFILE Keyword)
Model Outputs Separate Summary File of High Ranked Values (SUMMFILE Keyword)

**NOTE: The Following Flags May Appear Following CONC Values: c for Calm Hours
m for Missing Hours
b for Both Calm and Missing Hours

**Misc. Inputs: Base Elev. for Pot. Temp. Profile (m MSL) = 24.00 ; Decay Coef. = 0.000 ; Rot. Angle = 0.0
Emission Units = GRAMS/SEC ;
Emission Rate Unit Factor = 0.10000E+07
Output Units = MICROGRAMS/M**3

**Approximate Storage Requirements of Model = 3.6 MB of RAM.

**Input Runstream File: aermod.inp

**Output Print File: aermod.out

**Detailed Error/Message File: Phase4_Mitigated_11.3.err

**File for Summary of Results: Phase4_Mitigated_11.3.sum

```
 **Model Is Setup For Calculation of Average CONCentration Values.

   --  DEPOSITION LOGIC  --
 **NO GAS DEPOSITION Data Provided.
 **NO PARTICLE DEPOSITION Data Provided.
 **Model Uses NO DRY DEPLETION.  DRYDPLT  =  F
 **Model Uses NO WET DEPLETION.  WETDPLT  =  F

 **Model Uses RURAL Dispersion Only.

 **Model Uses Regulatory DEFAULT Options:
        1. Stack-tip Downwash.
        2. Model Accounts for ELEVated Terrain Effects.
        3. Use Calms Processing Routine.
        4. Use Missing Data Processing Routine.
        5. No Exponential Decay.

 **Other Options Specified:
        CCVR_Sub - Meteorological data includes CCVR substitutions
        TEMP_Sub - Meteorological data includes TEMP substitutions

 **Model Assumes No FLAGPOLE Receptor Heights.

 **The User Specified a Pollutant Type of:  PM_2.5

 **Model Calculates  1 Short Term Average(s) of:   1-HR
     and Calculates ANNUAL Averages

 **This Run Includes:      1 Source(s);       1 Source Group(s); and     841
Receptor(s)

                with:      0 POINT(s), including
                           0 POINTCAP(s) and      0 POINTHOR(s)
                 and:      0 VOLUME source(s)
                 and:      1 AREA type source(s)
                 and:      0 LINE source(s)
                 and:      0 OPENPIT source(s)
                 and:      0 BUOYANT LINE source(s) with      0 line(s)

 **Model Set To Continue RUNning After the Setup Testing.

 **The AERMET Input Meteorological Data Version Date:  14134

 **Output Options Selected:
         Model Outputs Tables of ANNUAL Averages by Receptor
         Model Outputs Tables of Highest Short Term Values by Receptor (RECTABLE
Keyword)
         Model Outputs External File(s) of High Values for Plotting (PLOTFILE
```

Keyword)
          Model Outputs Separate Summary File of High Ranked Values (SUMMFILE
Keyword)

 **NOTE: The Following Flags May Appear Following CONC Values: c for Calm Hours
                                                                 m for Missing
Hours
                                                                 b for Both Calm
and Missing Hours

 **Misc. Inputs: Base Elev. for Pot. Temp. Profile (m MSL) =   24.00 ; Decay
Coef. =   0.000   ; Rot. Angle =   0.0
                  Emission Units = GRAMS/SEC   ;
Emission Rate Unit Factor =   0.10000E+07
                  Output Units   = MICROGRAMS/M**3

 **Approximate Storage Requirements of Model =   3.6 MB of RAM.

 **Input Runstream File: aermod.inp

 **Output Print File: aermod.out

 **Detailed Error/Message File: Phase5_Mitigated_11.4.err

 **File for Summary of Results: Phase5_Mitigated_11.4.sum

```
 **Model Is Setup For Calculation of Average CONCentration Values.

   --  DEPOSITION LOGIC  --
 **NO GAS DEPOSITION Data Provided.
 **NO PARTICLE DEPOSITION Data Provided.
 **Model Uses NO DRY DEPLETION.  DRYDPLT  =  F
 **Model Uses NO WET DEPLETION.  WETDPLT  =  F

 **Model Uses RURAL Dispersion Only.

 **Model Uses Regulatory DEFAULT Options:
        1. Stack-tip Downwash.
        2. Model Accounts for ELEVated Terrain Effects.
        3. Use Calms Processing Routine.
        4. Use Missing Data Processing Routine.
        5. No Exponential Decay.

 **Other Options Specified:
        CCVR_Sub - Meteorological data includes CCVR substitutions
        TEMP_Sub - Meteorological data includes TEMP substitutions

 **Model Assumes No FLAGPOLE Receptor Heights.

 **The User Specified a Pollutant Type of:  PM_2.5

 **Model Calculates  1 Short Term Average(s) of:   1-HR
     and Calculates ANNUAL Averages

 **This Run Includes:      1 Source(s);       1 Source Group(s); and     841
Receptor(s)

                with:      0 POINT(s), including
                           0 POINTCAP(s) and      0 POINTHOR(s)
                 and:      0 VOLUME source(s)
                 and:      1 AREA type source(s)
                 and:      0 LINE source(s)
                 and:      0 OPENPIT source(s)
                 and:      0 BUOYANT LINE source(s) with      0 line(s)

 **Model Set To Continue RUNning After the Setup Testing.

 **The AERMET Input Meteorological Data Version Date:  14134

 **Output Options Selected:
         Model Outputs Tables of ANNUAL Averages by Receptor
         Model Outputs Tables of Highest Short Term Values by Receptor (RECTABLE
Keyword)
         Model Outputs External File(s) of High Values for Plotting (PLOTFILE
```

Keyword)
          Model Outputs Separate Summary File of High Ranked Values (SUMMFILE
Keyword)

 **NOTE: The Following Flags May Appear Following CONC Values: c for Calm Hours
                                                                 m for Missing
Hours
                                                                 b for Both Calm
and Missing Hours

 **Misc. Inputs: Base Elev. for Pot. Temp. Profile (m MSL) =   24.00 ; Decay
Coef. =   0.000   ; Rot. Angle =   0.0
                  Emission Units = GRAMS/SEC   ;
Emission Rate Unit Factor =   0.10000E+07
                  Output Units   = MICROGRAMS/M**3

 **Approximate Storage Requirements of Model =   3.6 MB of RAM.

 **Input Runstream File: aermod.inp

 **Output Print File: aermod.out

 **Detailed Error/Message File: Phase6_Mitigated_11.4.err

 **File for Summary of Results: Phase6_Mitigated_11.4.sum

  ***
 - - - - - - - - - - - - - - - - - - - - - - - - - - - - - - - - - - - - - - - -
- - - - - - - - - - - - - - - - - - - - - - -

 **Model Is Setup For Calculation of Average CONCentration Values.

   --  DEPOSITION LOGIC  --
 **NO GAS DEPOSITION Data Provided.
 **NO PARTICLE DEPOSITION Data Provided.
 **Model Uses NO DRY DEPLETION.  DRYDPLT  =  F
 **Model Uses NO WET DEPLETION.  WETDPLT  =  F

 **Model Uses RURAL Dispersion Only.

 **Model Uses Regulatory DEFAULT Options:
        1. Stack-tip Downwash.
        2. Model Accounts for ELEVated Terrain Effects.
        3. Use Calms Processing Routine.
        4. Use Missing Data Processing Routine.
        5. No Exponential Decay.

 **Other Options Specified:
        CCVR_Sub - Meteorological data includes CCVR substitutions
        TEMP_Sub - Meteorological data includes TEMP substitutions

 **Model Assumes No FLAGPOLE Receptor Heights.

 **The User Specified a Pollutant Type of:  PM_2.5

 **Model Calculates  1 Short Term Average(s) of:   1-HR
     and Calculates ANNUAL Averages

 **This Run Includes:      1 Source(s);       1 Source Group(s); and     841
Receptor(s)

                with:      0 POINT(s), including
                           0 POINTCAP(s) and      0 POINTHOR(s)
                 and:      0 VOLUME source(s)
                 and:      1 AREA type source(s)
                 and:      0 LINE source(s)
                 and:      0 OPENPIT source(s)
                 and:      0 BUOYANT LINE source(s) with      0 line(s)

 **Model Set To Continue RUNning After the Setup Testing.

 **The AERMET Input Meteorological Data Version Date:  14134

 **Output Options Selected:
         Model Outputs Tables of ANNUAL Averages by Receptor
```

```
          Model Outputs Tables of Highest Short Term Values by Receptor (RECTABLE
Keyword)
          Model Outputs External File(s) of High Values for Plotting (PLOTFILE
Keyword)
          Model Outputs Separate Summary File of High Ranked Values (SUMMFILE
Keyword)

 **NOTE:  The Following Flags May Appear Following CONC Values:  c for Calm Hours
                                                                 m for Missing
Hours
                                                                 b for Both Calm
and Missing Hours

 **Misc. Inputs:  Base Elev. for Pot. Temp. Profile (m MSL) =    24.00 ;  Decay
Coef. =    0.000     ;  Rot. Angle =     0.0
                  Emission Units = GRAMS/SEC                                ;
Emission Rate Unit Factor =   0.10000E+07
                  Output Units   = MICROGRAMS/M**3

 **Approximate Storage Requirements of Model =      3.6 MB of RAM.

 **Input Runstream File:          aermod.inp

 **Output Print File:             aermod.out

 **Detailed Error/Message File:   PHASE 2 AND 3 OPERATION.err

 **File for Summary of Results:   PHASE 2 AND 3 OPERATION.sum

Model Outputs Tables of ANNUAL Averages by Receptor
Model Outputs Tables of Highest Short Term Values by Receptor (RECTABLE Keyword)
Model Outputs External File(s) of High Values for Plotting (PLOTFILE Keyword)
Model Outputs Separate Summary File of High Ranked Values (SUMMFILE Keyword)

**NOTE: The Following Flags May Appear Following CONC Values: c for Calm Hours
m for Missing Hours
b for Both Calm and Missing Hours

**Misc. Inputs: Base Elev. for Pot. Temp. Profile (m MSL) = 24.00 ; Decay Coef. = 0.000 ; Rot. Angle = 0.0
Emission Units = GRAMS/SEC ;
Emission Rate Unit Factor = 0.10000E+07
Output Units = MICROGRAMS/M**3

**Approximate Storage Requirements of Model = 3.6 MB of RAM.

**Input Runstream File: aermod.inp

**Output Print File: aermod.out

**Detailed Error/Message File: Hitch Ranch_Phase 4_Operation.err

**File for Summary of Results: Hitch Ranch_Phase 4_Operation.sum

 **Model Is Setup For Calculation of Average CONCentration Values.

   --  DEPOSITION LOGIC  --
 **NO GAS DEPOSITION Data Provided.
 **NO PARTICLE DEPOSITION Data Provided.
 **Model Uses NO DRY DEPLETION.  DRYDPLT  =  F
 **Model Uses NO WET DEPLETION.  WETDPLT  =  F

 **Model Uses RURAL Dispersion Only.

 **Model Uses Regulatory DEFAULT Options:
        1. Stack-tip Downwash.
        2. Model Accounts for ELEVated Terrain Effects.
        3. Use Calms Processing Routine.
        4. Use Missing Data Processing Routine.
        5. No Exponential Decay.

 **Other Options Specified:
        CCVR_Sub - Meteorological data includes CCVR substitutions
        TEMP_Sub - Meteorological data includes TEMP substitutions

 **Model Assumes No FLAGPOLE Receptor Heights.

 **The User Specified a Pollutant Type of:  PM_2.5

 **Model Calculates  1 Short Term Average(s) of:   1-HR
     and Calculates ANNUAL Averages

 **This Run Includes:      1 Source(s);       1 Source Group(s); and     711
Receptor(s)

                with:      0 POINT(s), including
                           0 POINTCAP(s) and      0 POINTHOR(s)
                 and:      0 VOLUME source(s)
                 and:      1 AREA type source(s)
                 and:      0 LINE source(s)
                 and:      0 OPENPIT source(s)
                 and:      0 BUOYANT LINE source(s) with      0 line(s)

 **Model Set To Continue RUNning After the Setup Testing.

 **The AERMET Input Meteorological Data Version Date:  14134

 **Output Options Selected:
         Model Outputs Tables of ANNUAL Averages by Receptor
         Model Outputs Tables of Highest Short Term Values by Receptor (RECTABLE
Keyword)
```

Model Outputs External File(s) of High Values for Plotting (PLOTFILE Keyword)
Model Outputs Separate Summary File of High Ranked Values (SUMMFILE Keyword)

**NOTE: The Following Flags May Appear Following CONC Values: c for Calm Hours
m for Missing Hours
b for Both Calm and Missing Hours

**Misc. Inputs: Base Elev. for Pot. Temp. Profile (m MSL) = 24.00 ; Decay Coef. = 0.000 ; Rot. Angle = 0.0
Emission Units = GRAMS/SEC ;
Emission Rate Unit Factor = 0.10000E+07
Output Units = MICROGRAMS/M**3

**Approximate Storage Requirements of Model = 3.6 MB of RAM.

**Input Runstream File: aermod.inp

**Output Print File: aermod.out

**Detailed Error/Message File: Hitch Ranch_Phase 5_Operation.err

**File for Summary of Results: Hitch Ranch_Phase 5_Operation.sum

Model Outputs Tables of ANNUAL Averages by Receptor
Model Outputs Tables of Highest Short Term Values by Receptor (RECTABLE Keyword)
Model Outputs External File(s) of High Values for Plotting (PLOTFILE Keyword)
Model Outputs Separate Summary File of High Ranked Values (SUMMFILE Keyword)

**NOTE: The Following Flags May Appear Following CONC Values: c for Calm Hours
m for Missing Hours
b for Both Calm and Missing Hours

**Misc. Inputs: Base Elev. for Pot. Temp. Profile (m MSL) = 24.00 ; Decay Coef. = 0.000 ; Rot. Angle = 0.0
Emission Units = GRAMS/SEC ;
Emission Rate Unit Factor = 0.10000E+07
Output Units = MICROGRAMS/M**3

**Approximate Storage Requirements of Model = 3.6 MB of RAM.

**Input Runstream File: aermod.inp

**Output Print File: aermod.out

**Detailed Error/Message File: Hitch Ranch_Phase 6_Operational.err

**File for Summary of Results: Hitch Ranch_Phase 6_Operational.sum

SUMMARY

This report updates the biological elements and potential effects documented to date for the Hitch Ranch Specific Plan site, as presented in the November 2008 Draft EIR (DEIR). Biological issues reassessed include the potential for special-status plant and animal species to be present, presence of active bird nests, and observations of the general vegetation communities and wildlife species that inhabit the proposed project area.

This report concurs with the findings presented in the DEIR for the following factors: special-status plant species; protected trees; special-status animals including western spadefoot, coastal whiptail, coast horned lizard, southern California rufous-crowned sparrow, Bell's sage sparrow, white-tailed kite, horned lark, loggerhead shrike, San Diego black-tailed jackrabbit; and U.S. Army Corps of Engineers (USACE) and California Department of Fish and Wildlife (CDFW) jurisdictional resources.

In addition, this report agrees with the potential for significant impacts resulting from project implementation that was predicted by previous biological survey reports including adverse effects to special-status animals including coast patch-nosed snake, grasshopper sparrow, burrowing owl, Costa's hummingbird, Allen's hummingbird, San Diego desert woodrat, and American badger. Implementation of the DEIR-proposed mitigation measures would reduce potential impacts to coast patch-nosed snake, grasshopper sparrow, Costa's hummingbird, and Allen's hummingbird to a level of less than significant. However, potential impacts to burrowing owl, San Diego desert woodrat, and American badger would remain significant. Additional mitigation measures proposed in the 2009 Updated Report of Potential for Special-status Species on the Hitch Ranch Project Site by Impact Sciences would further reduce impacts to these three species to a less than significant level and are also recommended by this report.

BACKGROUND

The DEIR for the 277-acre proposed project was prepared in draft form by Impact Sciences in November 2008 and has since been revised through corrections, additions, and responses to public comments.

Impact Sciences initially conducted a general biological survey on the site on September 12, 1993. The plant communities on the site were mapped, characterized, and analyzed for their potential to support special-status species.

Mike Starr of Nature Buffs conducted a survey in 1995 of all trees on the site that had trunks of at least 4 inches in diameter at 4.5 feet above grade (also referred to as diameter at breast height or DBH). The trees meeting this criterion were tagged and mapped in the field. Subsequent field surveys to update the 1995 tree survey were conducted in 2001 by Impact Sciences and in 2011 by Rincon Consultants, Inc. and a

new tree map of the site was created. In addition, Rincon included tree canopy heights and widths and health assessments. This survey was referenced for the 2018 and 2019 biological survey updates. Only one native California black walnut tree was identified and mapped during the 2011 tree survey.

Since a wildfire occurred on the project site in 2003, Impact Sciences characterized and mapped the plant communities again on September 28, 2006, to update and evaluate the habitat conditions on the project site and to assist in determining the potential of each habitat to support special-status species. Shortly after the plant communities were characterized in 2006, another fire burned the entire property, and an additional site visit was made in January 2007 to assess the effects of the fire on trees and plant communities on site.

Focused plant surveys were conducted on April 21, 22, and 29, and May 15 1998, and again in May and June of 2000 to update the information obtained during the initial 1993 surveys. Following the 2003 fire, additional focused plant surveys were conducted by Impact Sciences in the spring of 2006. Special attention was afforded to those portions of the site potentially supporting sensitive flora or fauna. Three additional focused plant surveys were conducted in spring 2016 and a report submitted. In the July 2016 Focused Special Status Plant Survey Report, several native southern California black walnut (*Juglans californica* [var. *californica*]) trees were found in the western area of the property, east of and within about 300 feet of Gabbert Road. These trees were not individually mapped and it was concluded that they "do not form a woodland, since they are scattered over a large area". California walnut woodlands (*Juglans californica* woodland alliance) have a rarity ranking of G3 S3.2, indicating this species is "vulnerable" throughout its range and "threatened" within California. However, it was recommended that a tree survey be conducted to establish precise locations of these trees such that appropriate protection zones may be defined because native walnut trees should be avoided.

Protocol surveys for coastal California gnatcatcher (*Polioptila californica californica*), a federally listed threatened bird species, were performed in 1998, 2000, 2003, 2005, 2009, and 2011 and reports submitted. All surveys were conducted in accordance with U.S. Fish and Wildlife Service (USFWS) survey protocols, which require that six surveys be conducted at least one week apart from March 15 through June 30, or a minimum of nine surveys at least two weeks apart be conducted July 1 through March 14. Even though one potential migrant bird was observed, no California gnatcatchers were suspected of using the site for important life history periods (e.g., nesting).

General wildlife surveys were conducted concurrent with the vegetation mapping, tree surveys, and focused plant and animal surveys. All common animals and sign of presence (scat, tracks, burrows, and trails) observed were noted during all visits to the site, including in 2018.

METHODOLOGY

Barringer Biological Services' principal biologist Debra Barringer conducted a field visit on April 12, 2019, at the Hitch Ranch project site (site). Because of the long history of previous studies and documentation that has been completed for the subject site, the goal of the April 2019 field visit was to confirm whether conditions had remained the same on the site or had changed since the preparation of the 2008 DEIR, and to further update the conclusions regarding the potential of special-status and protected species to utilize the site. Focus was also given to finding and mapping the southern California black walnut trees identified in the July 2016 Focused Special Status Plant Survey Report and to observing active bird nesting sites.

The April 2019 site visit was conducted under clear skies with temperatures ranging from 54 to 80 degrees Fahrenheit. The site was traversed by foot focusing on the areas not as thoroughly covered during the 2018 survey, which focused on health assessments for the previously mapped trees. Data including all wildlife observed and heard were recorded, photos taken, breeding activity at nests observed, and GPS points taken for newly identified special status trees.

Because of the extensive survey history that has included at least 10 focused plant surveys and 6 protocol surveys for coastal California gnatcatcher, the purpose of the 2019 survey was to identify if the potential for on-site habitats to support special-status plant or animal species had changed. Focused surveys for particular plant and animal species were not conducted other than to document the southern California black walnut trees. The determination of potential for special-status species to be present on the project site is based on the proximity of the site to recorded occurrences from the CNDDB and CNPS databases, on-site vegetation and habitat characteristics, topography, elevation, soils, surrounding land uses, and known habitat requirements and geographic ranges of special-status plant and animal species known to occur in the region.

EXISTING CONDITIONS

Region and Local

Regionally, the project site is located in southeastern Ventura County between the Simi Hills and Little Simi Valley. Locally, the project site is located in the open space north of Poindexter Avenue and west of Moorpark Road (State Route 23) and Walnut Canyon Elementary School. Specifically, the site is approximately 285.1 acres, is located approximately 1,600 feet west of State Route 23, and extends approximately 1,400 feet west of Gabbert Road.

The project site is situated within the Transverse Ranges at the southern limit of the Simi Hills, between the Oak Ridge Mountains to the north and the Las Posas Hills to the south. Various densities of development surround the site, with the railroad and Poindexter Avenue adjacent to the south boundary, light industrial and residential uses south of Poindexter Avenue, rural residential and Walnut Canyon School to the east, and rural residential uses and a Southern California Edison transmission corridor to the west (see Figure 1 for an October 2016 aerial photo). A large paved parkway has been constructed north of the site, which ends at the Hitch Ranch boundary.

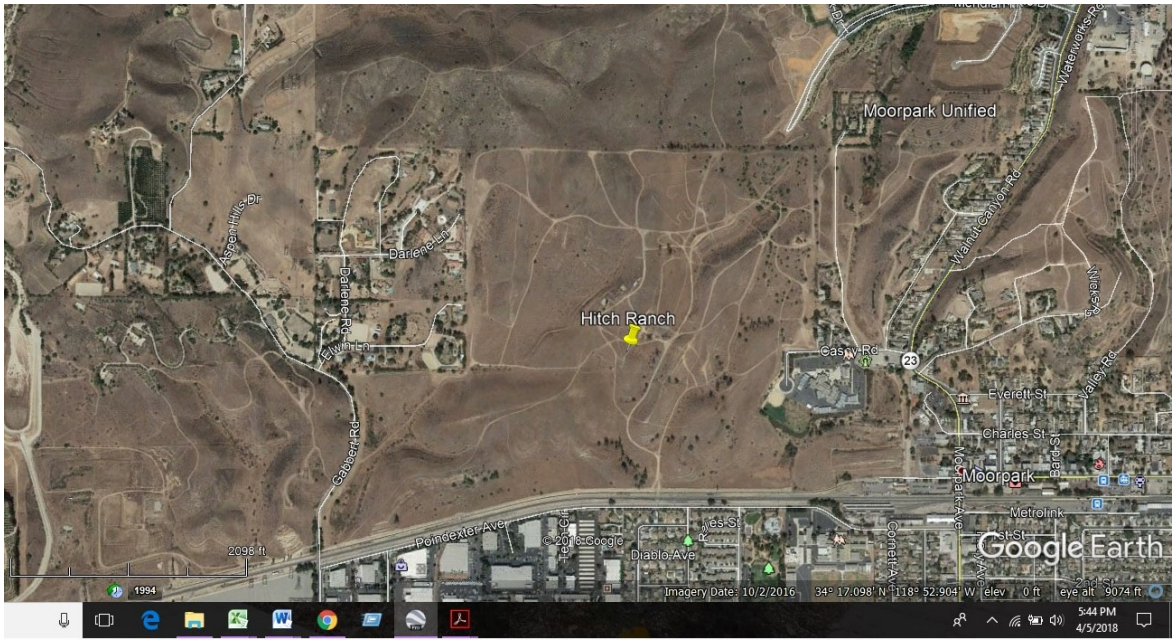

Figure 1. Aerial view from October 2016 of the Hitch Ranch project site showing surrounding development

The site is characterized by gently rolling hills and a series of north-south trending ridges and canyons. The topography ranges from moderately hilly to relatively flat; elevation at the site ranges from approximately 475 to 720 feet above mean sea level. The site has been previously disturbed by agricultural operations including orchards and grazing, and two fires. Numerous dirt roads, concrete foundations of old farm buildings, and culverts in old agricultural ditches are still present. The vegetation is primarily annual grassland, with scattered California sagebrush-deerweed, coyote brush scrub, mulefat scrub, and non- native woodland communities. In 2003 and 2006, fires entirely burned these plant communities. Since the 2006 fire, these communities have recovered to their pre-fire condition but nonnative grasses and forbs dominate much of the site. Several ephemeral drainages convey storm water down the steep slopes of the site, but no defined beds and banks or well-developed riparian plant communities are present.

Vegetation

Vegetation at the project site was assessed and described in Section 3.3, Biology, of the November 2008 DEIR for the project and has been updated regularly since. The Biology section included a vegetation map (Figure 3.3-2 in the DEIR), which continues to depict current general habitat conditions. According to the Biology section and Figure 3.3-2, the project site supports the following habitat types:

- annual [non-native] grassland – 129 acres
- annual grassland/coyotebush scrub – 3.9 acres
- ornamental [non-native] woodland – 27.4 acres
- California sagebrush-deerweed scrub – 30. 6 acres
- coyotebush scrub – 58.3 acres
- mulefat scrub – 0.9 acres
- barren [non-vegetated] areas – 36.3 acres

During the 2019 biological survey, cattle were grazing in the area mapped as coyote brush scrub, which was at the time dominated by grasses and forbs.

USACE Jurisdictional Resources

Several drainages traverse the site in a north-south direction. The largest is a sandy wash in the western portion of the site, west of Gabbert Road. A defined stream channel (i.e., bed and bank) was not observed at this location; however mulefat and elderberry, both of which are classified as hydrophytic (wetland) indicator plants, grow within this sandy wash.

An erosional feature was noted during the 2018 survey in the northeast portion of the site that likely drains from land disturbance north of the project boundary. As in 2018, recent heavy runoff in 2019 seems to have eroded the drainage even further (see Figure 2). In addition, evidence of runoff in the drainage that parallels Gabbert Road was also observed in 2019 (Figure 3).

Figure 2. Erosional feature in northwest project site

Figure 3. Evidence of recent flow along east side of Gabbert Road in project site

General Wildlife

Wildlife species observed during the 2019 site survey are presented in Table A1 of Appendix 1. These species overlap with those seen during other surveys in the past and represent typical species known to utilize the site during at least a portion of their life histories.

RESULTS AND RECOMMENDATIONS

Sensitive Plant Community – California Sagebrush-Deerweed Scrub

California sagebrush-deerweed scrub is a sub-type of coastal sage scrub, and as such is protected locally under the Ventura County General Plan. The DEIR indicates that approximately 30.6 acres of this vegetation type were present in the western portion of the project site. This assessment remained accurate as of the June 2009 survey and these California sagebrush-deerweed scrub patches have further matured by spring 2019.

Special-Status and Protected Species and Resources

The DEIR disclosed the presence of one special-status plant species and seven special-status animal species observed on the project site. An additional 22 special-status plants and 36 special-status animal species were evaluated in the DEIR for their potential to utilize the site based on site habitat characteristics and species ranges, habitat requirements and known records in the project region.

Additional species were considered in more detail in the 2009 Hitch Ranch Special-Status Species Update report due to new information in the CNPS and CNDDB database, as well as considerations for species not reported in those databases but with potential to be present on the project site due to habitat and range attributes. In that report, a thorough analysis of the potential for these special-status species to utilize the site was conducted. In the event that these species are present prior to project implementation, additional recommendations for minimizing impacts were included. The 2019 project site survey and analysis found no evidence that these assessments have changed to a significant degree and, therefore, conclusions and recommendations presented in the 2009 report are fully supported.

Special-Status Plant Species

Southern California black walnut (*Juglans californica* var. *californica*) -- CNPS List 4.2 (*limited distribution*) – During the April 2019 survey, eight additional California black walnut trees to the one that was listed in the Rincon 2011 tree survey report were identified and recorded along with data on stem diameters and heights. Global positioning systems (GPS) points were taken at each tree clump that were all observed in the western portion of the project site east of Gabbert Road. Locations were added to the Rincon tree survey map (Figure 4) as green dots. The white numbers do not coincide with the new tree locations. New numbers were assigned and the tree data recorded are listed in Table A2 Results of the 2019 Supplemental Protected Tree Survey and Health Assessment Update in Appendix 2. These native California trees provide many values to local wildlife and every effort should be made to protect them during project implementation.

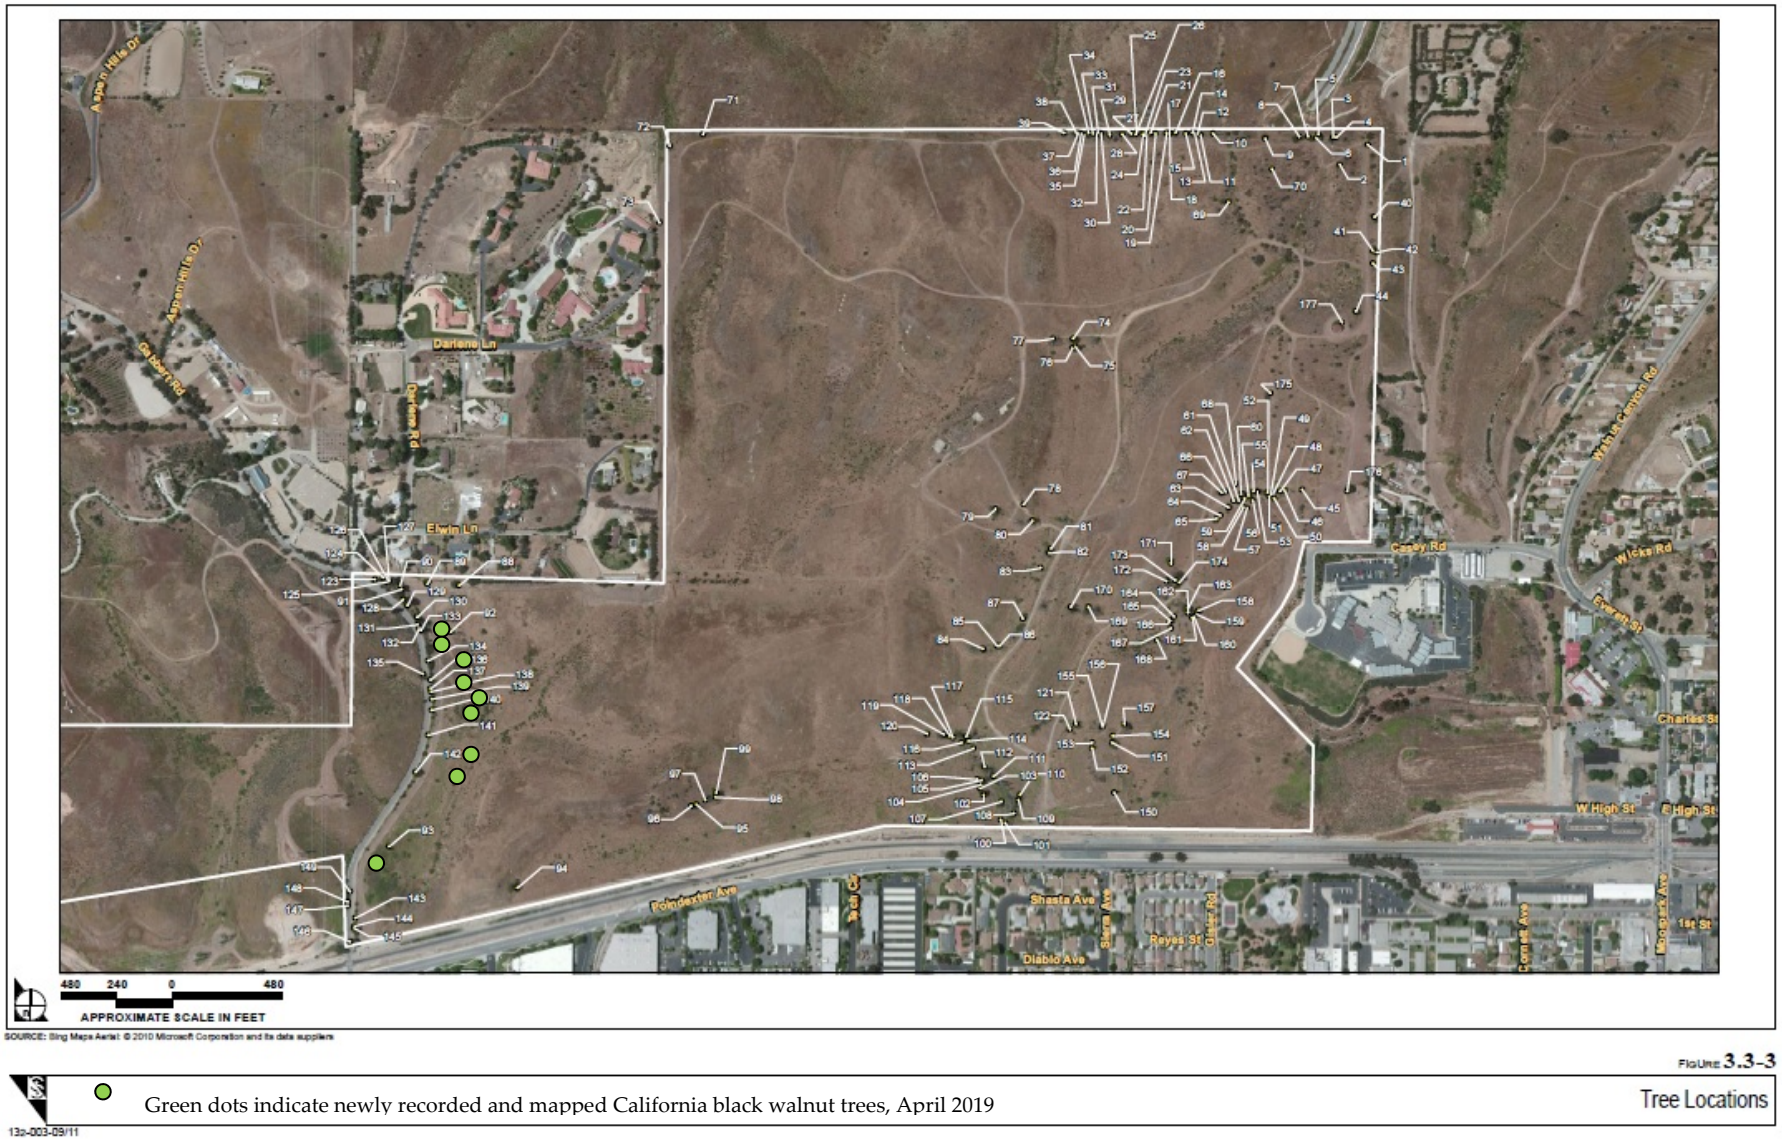

Figure 4. Amended Rincon 2011 Tree Survey Map of the Hitch Ranch Project Site

Locally Protected Trees

Mature non-native trees, which are of local special interest, are present on the site. The City of Moorpark tree ordinance (under Chapter 12.12 Historic Trees, Native Oak Trees and Mature Trees 14.09.010—14.09.140, [12.12] No. 101) provides for the protection of all species of mature trees with a cross-sectional area of all major stems of 72 or more square inches (equivalent to 9.6 inches diameter at breast height [DBH]), as measured at 4.5 feet above the root crown. As previously stated, the original tree survey was conducted on the site in 1995 (Nature Buffs). A total of 528 trees were observed during the survey that qualified as mature trees, including gum, pepper, olive (*Olea europaea*), ash (*Fraxinus* sp.), tamarisk (*Tamarix* sp.), African sumac (*Rhus lancea*), and walnut. Most of these trees were affected by the 2003 and 2006 fires. Those on the interior of the site were completely burned, but many of the trees that line the edge of the site were only partially burned and many have since recovered.

The 2018 biological survey reassessed the presence and health of remaining mature trees using the numbering system and mapping from a thorough tree survey conducted in 2011 by Rincon (Figure 4). These update data were presented in Table A2 of Appendix 2 of the Hitch Ranch Project City of Moorpark, Ventura County, California 2018 Biological Survey Update. Those survey results indicated that 143 mature trees remained alive and therefore still qualify under the Moorpark ordinance for consideration for preservation. The biological survey update in 2019 confirmed that conditions remain the same and the mapped trees have continued to recover due to above-average precipitation during winter 2018-2019. In addition, eight more native California black walnut trees were observed and recorded that all qualify as mature trees for a total of 151 trees that require protection and/or mitigation.

Special-Status Wildlife

The DEIR concluded that 16 special-status species either utilize or could potentially utilize the project site, and 12 of these species had the potential for significant impacts to some portion of their life history upon project implementation. The DEIR proposed mitigation measures for the latter species. The 2009 Hitch Ranch Special-Status Species Update report made additional conclusions and mitigation suggestions for seven other species that would reduce potential impacts to less than significant. This report concurs with these findings. Table 1 summarizes these conclusions and recommendations.

A Cooper's hawk was observed on the site in both 2018 and 2019 during the breeding season in the same general area, indicating very likely a nesting pair on or near the ranch. Cooper's hawks are state special status species. Additionally, active nests of all native bird species are protected under federal and state laws. In addition, during the 2019 survey an active red-tailed hawk nest was observed on the northern project site border that contained three nestlings. If ground disturbance including vegetation removal, is

commenced during breeding season, buffers of usually 500 feet for raptors need to be established around active nests until the young have fledged and are no longer using the nest

Table 1. Impact Conclusions for Sensitive Wildlife Species Analyzed in Past Studies and the DEIR

Coastal whiptail	Yes	Yes
Coast horned lizard	Yes	Yes
California horned lizard	Yes	Yes
White-tailed kite	Yes	Yes
Cooper's hawk	Yes	Yes
California rufous-crowned sparrow	Yes	Yes
Loggerhead shrike	Yes	Yes
Yellow-breasted chat	No, no nesting habitat on site	NA
Sharp-shinned hawk	No, no nesting habitat on site	NA
Ferruginous hawk	No, no nesting habitat on site	NA
Northern harrier	Yes	Yes
Prairie falcon	No, no nesting habitat on site	NA
Bell's sage sparrow	Yes	Yes
California horned lark	Yes	Yes
San Diego black-tailed jackrabbit	Yes	Yes
Additional Species That Were Not Evaluated or not Anticipated to be Affected in the DEIR That May Utilize the Project Site	**Potential Impacts**	**Mitigation Measures Proposed in the 2009 Special-status Species Update to Address Potential Impacts**
Coast patch-nosed snake	Yes	Covered by DEIR mitigation measures
Grasshopper sparrow	Yes	Covered by DEIR mitigation measures
Burrowing owl	Yes, however mitigatable to *less than significant*	Preconstruction nesting or winter surveys and protection of occupied burrows until nestlings have fledged or wintering birds have been safely excluded from the burrows.
Costa's hummingbird	Yes	Covered by DEIR mitigation measures
Allen's hummingbird	Yes	Covered by DEIR mitigation measures
San Diego desert woodrat	Yes, however mitigatable to *less than significant*	Preconstruction focused surveys for woodrats and nests; either protection of nests or relocation of woodrats and nesting material.
American badger	Yes, however mitigatable to *less than significant*	Preconstruction focused surveys for denning sites and delay of nearby construction activities until young are weaned and leave the den.

USACE Jurisdictional Resources

Several drainages occur throughout the site, the largest of which occurs along a sandy wash in the western portion of the site, west of Gabbert Road. A defined stream channel was not identified at this location, but plant wetland-indicators grow within this sandy wash. This or other drainages, including the erosional feature in the northeastern portion of the site, may qualify as USACE jurisdictional resources. Therefore, a formal wetland delineation should be conducted pursuant to USACE survey protocols and a subsequent agency jurisdictional determination made, and if applicable, impacts quantified. If part of the proposed project actions, the discharge of fill into USACE-jurisdictional waters would likely require a permit pursuant to Section 404 of the Clean Water Act. Any modification to a streambed, if present, including removal of riparian vegetation, may require a streambed alteration agreement from CDFW pursuant to Section 1602 of the *California Fish and Game Code*. The Regional Water Quality Control Board also certifies USACE Section 404 permits and regulates discharge of fill into "waters of the United States" to ensure that Section 401 Clean Water Act or waste discharge under the Porter-Cologne Act criteria are met.

SUMMARY

This report updates the biological elements and potential effects documented to date for the Hitch Ranch Specific Plan site, as presented in the November 2008 Draft EIR (DEIR). Biological issues reassessed include the potential for special-status species to be present, presence of City of Moorpark-designated trees to be preserved, and observations of the general vegetation communities and wildlife species that inhabit the proposed project area.

This report concurs with the findings presented in the DEIR for the following factors: special-status plant species; protected trees; special-status animals including western spadefoot, coastal whiptail, coast horned lizard, southern California rufous-crowned sparrow, Bell's sage sparrow, white-tailed kite, horned lark, loggerhead shrike, San Diego black-tailed jackrabbit; and U.S. Army Corps of Engineers (USACE) and California Department of Fish and Wildlife (CDFW) jurisdictional resources.

In addition, this report agrees with the potential for significant impacts resulting from project implementation that was predicted by previous biological survey reports including adverse effects to special-status animals including coast patch-nosed snake, grasshopper sparrow, burrowing owl, Costa's hummingbird, Allen's hummingbird, San Diego desert woodrat, and American badger. Implementation of the DEIR-proposed mitigation measures would reduce potential impacts to coast patch-nosed snake, grasshopper sparrow, Costa's hummingbird, and Allen's hummingbird to a level of less than significant. However, potential impacts to burrowing owl, San Diego desert woodrat, and American badger would remain significant. Additional mitigation measures proposed in the 2009 Updated Report of Potential for Special-status Species on the Hitch Ranch Project Site by Impact Sciences would further reduce impacts to these three species to a less than significant level and are also recommended by this report.

BACKGROUND

The DEIR for the proposed project was prepared in draft form by Impact Sciences in November 2008 and has since been revised through corrections, additions, and responses to public comments.

Impact Sciences initially conducted a general biological survey on the site on September 12, 1993. The plant communities on the site were mapped, characterized, and analyzed for their potential to support special-status species.

Mike Starr of Nature Buffs conducted a survey in 1995 of all trees on the site that had trunks of at least 4 inches in diameter at 4.5 feet above grade (also referred to as diameter at breast height or dbh and comparable to a cross sectional area of 72 in^2). The trees meeting this criterion were tagged and mapped in the field. Subsequent field surveys to update the 1995 tree survey were conducted in 2001 by Impact

Sciences and in 2011 by Rincon Consultants, Inc. and a new tree map of the site was created. In addition, Rincon included tree canopy heights and widths and health assessments. This survey was referenced for the current 2018 biological survey and update.

Since a wildfire occurred on the project site in 2003, Impact Sciences characterized and mapped the plant communities again on September 28, 2006, to update and evaluate the habitat conditions on the project site and to assist in determining the potential of each habitat to support special-status species. Shortly after the plant communities were characterized in 2006, another fire burned the entire property, and an additional site visit was made in January 2007 to assess the effects of the fire on trees and plant communities on site.

Focused plant surveys were conducted on April 21, 22, and 29, and May 15 1998, and again in May and June of 2000 to update the information obtained during the initial 1993 surveys. Following the 2003 fire, additional focused plant surveys were conducted by Impact Sciences in the spring of 2006. Special attention was afforded to those portions of the site potentially supporting sensitive flora or fauna. Three additional focused plant surveys were conducted in spring 2016 and a report submitted.

Protocol surveys for coastal California gnatcatcher (*Polioptila californica californica*), a federally listed threatened bird species, were performed in 1998, 2000, 2003, 2005, 2009, and 2011 and reports submitted. All surveys were conducted in accordance with U.S. Fish and Wildlife Service (USFWS) survey protocols, which require that six surveys be conducted at least one week apart from March 15 through June 30, or a minimum of nine surveys at least two weeks apart be conducted July 1 through March 14. Even though one potential migrant bird was observed, no California gnatcatchers were suspected of using the site for important life history periods (e.g., nesting).

General wildlife surveys were conducted concurrent with the vegetation mapping, tree surveys, and focused plant and animal surveys. All common animals and sign of presence (scat, tracks, burrows, and trails) observed were noted during all visits to the site, including in 2018.

METHODOLOGY

Barringer Biological Services' principal biologist Debra Barringer conducted a field visit on April 3, 2018, at the Hitch Ranch project site (site). Because of the long history of previous studies and documentation that has been completed for the subject site, the goal of the April 2018 field visit was to confirm whether conditions had remained the same on the site or had changed since the preparation of the 2008 DEIR, and to further update the conclusions regarding the potential of special-status and protected species to utilize the site.

Prior to the April 2018 site visit, the previous survey reports, the CDFW California Natural Diversity Database (CNDDB), and the California Native Plant Society (CNPS) Inventory of Rare and Endangered Plants were reviewed to identify special-status plant or animal species known to occur in the area. The CNDDB lists historical and recently recorded occurrences of special-status plant and animal species, and the CNPS database lists historical and recent occurrences of special-status plant species. The database searches included the Moorpark U.S. Geological Survey (USGS) 7.5-minute quadrangle, in which the project site is located, as well as the seven surrounding quadrangles: Thousand Oaks, Newbury Park, Santa Paula, Santa Paula Peak, Camarillo, Simi, Piru, and Fillmore.

The April 2018 site visit was conducted under hazy skies through the morning with temperatures of approximately 59 to 66 degrees Fahrenheit. The site was traversed by foot focusing on the areas with protected trees to update their status. The 2011 Rincon tree map was used to the extent possible to locate and identify protected trees on site – no number tags were found on trees. Data including tree presence, and whether the tree remained alive and/or was burned was collected, and general health of the tree using the grades A through D developed by Rincon was re-assessed.

Because of the extensive survey history that has included at least 10 focused plant surveys and 6 protocol surveys for coastal California gnatcatcher, the purpose of the 2018 survey was to identify if the potential for on-site habitats to support special-status plant or animal species had changed; therefore, focused or detailed surveys for particular plant and animal species were not conducted. The determination of potential for special-status species to be present on the project site is based on the proximity of the site to recorded occurrences from the CNDDB and CNPS databases, on-site vegetation and habitat characteristics, topography, elevation, soils, surrounding land uses, and known habitat requirements and geographic ranges of special-status plant and animal species known to occur in the region.

EXISTING CONDITIONS

Region and Local

Regionally, the project site is located in southeastern Ventura County between the Simi Hills and Little Simi Valley. Locally, the project site is located in the open space north of Poindexter Avenue and west of Moorpark Road (State Route 23) and Walnut Canyon Elementary School. Specifically, the site is approximately 285.1 acres, is located approximately 1,600 feet west of State Route 23, and extends approximately 1,400 feet west of Gabbert Road.

The project site is situated within the Transverse Ranges at the southern limit of the Simi Hills, between the Oak Ridge Mountains to the north and the Las Posas Hills to the south. Various densities of development surround the site, with the railroad and Poindexter Avenue adjacent to the south boundary,

light industrial and residential uses south of Poindexter Avenue, rural residential and Walnut Canyon School to the east, and rural residential uses and a Southern California Edison transmission corridor to the west (see Figure 1 for an October 2016 aerial photo). A large paved parkway has been constructed north of the site, which ends at the Hitch Ranch boundary.

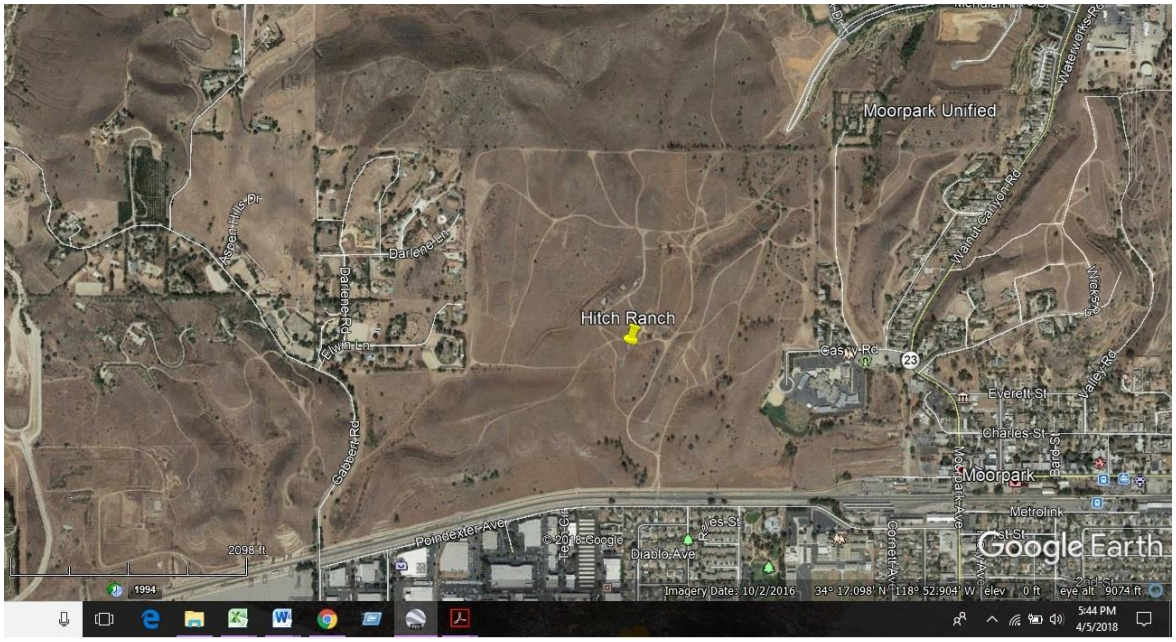

Figure 1. Recent aerial view (10/2/2016) of the Hitch Ranch project site showing surrounding development

The site is characterized by gently rolling hills and a series of north-south trending ridges and canyons. The topography ranges from moderately hilly to relatively flat; elevation at the site ranges from approximately 475 to 720 feet above mean sea level. The site has been previously disturbed by agricultural operations including orchards and grazing, and two fires. Numerous dirt roads, concrete foundations of old farm buildings, and culverts in old agricultural ditches are still present. The vegetation is primarily annual grassland (including that mixed with coyote brush scrub), with scattered California sagebrush-deerweed, coyote brush scrub, mulefat scrub, and non- native woodland communities. In 2003 and 2006, fires entirely burned these plant communities. Since the 2006 fire, these communities have recovered to their pre-fire condition. Several ephemeral drainages convey storm water down the steep slopes of the site, but no defined beds and banks or well-developed riparian plant communities are present.

Vegetation

Vegetation at the project site was assessed and described in Section 3.3, Biology, of the November 2008 DEIR for the project. The Biology section included a vegetation map (Figure 3.3-1 in the DEIR), which continues to depict current general habitat conditions. According to the Biology section and Figure 3.3-1, the project site supports the following habitat types:

- annual [non-native] grassland – 129 acres
- annual grassland/coyotebush scrub – 3.9 acres
- ornamental [non-native] woodland – 27.4 acres
- California sagebrush-deerweed scrub – 30. 6 acres
- coyotebush scrub – 58.3 acres
- mulefat scrub – 0.9 acres
- barren [non-vegetated] areas – 36.3 acres

USACE Jurisdictional Resources

Several drainages traverse the site in a north-south direction. The largest is a sandy wash in the western portion of the site, west of Gabbert Road. A defined stream channel (i.e., bed and bank) was not observed at this location; however mulefat and elderberry, both of which are classified as hydrophytic (wetland) indicator plants, grow within this sandy wash.

An erosional feature was noted during the 2018 survey in the northeast portion of the site that likely drains from land disturbance north of the project boundary. Recent heavy runoff caused soil to wash out and further expose a buried pipe (see Figure 2).

Figure 2. Erosional feature in northwest project site.

General Wildlife

Wildlife species observed on site during the 2018 site survey are presented in Table A1 of Appendix 1. These species overlap with those seen during other surveys in the past and represent typical species known to utilize the site during at least a portion of their life histories.

RESULTS AND RECOMMENDATIONS

Sensitive Plant Community – California Sagebrush-Deerweed Scrub

California sagebrush-deerweed scrub is a sub-type of coastal sage scrub, and as such is protected locally under the Ventura County General Plan. The DEIR indicates that approximately 30.6 acres of this vegetation type were present in the western portion of the project site. This assessment remained accurate as of the June 2009 survey and these California sagebrush-deerweed scrub patches have further matured by spring 2018.

Special-status and Protected Species and Resources

The DEIR disclosed the presence of one special-status plant and seven special-status animal species observed on the project site. An additional 22 special-status plants and 36 special-status animal species were evaluated in the DEIR for their potential to utilize the site based on site habitat characteristics and species ranges, habitat requirements and known records in the project region.

Additional species were considered in more detail in the 2009 Hitch Ranch Special-status Species Update report due to new information in the CNPS and CNDDB database, as well as considerations for species not reported in those databases but with potential to be present on the project site due to habitat and range attributes. In that report, a thorough analysis of the potential for these special-status species to utilize the site was conducted. In the event that these species are present prior to project implementation, additional recommendations for minimizing impacts were included. The 2018 project site survey and analysis found no evidence that these assessments have changed to a significant degree and, therefore, conclusions and recommendations presented in the 2009 report are fully supported.

Special-Status Plant Species

Southern California black walnut (*Juglans californica* var. *californica*) -- CNPS List 4.2 (*limited distribution*) -- One California black walnut tree clump with a combined dbh greater than 8 inches was observed within the coyote brush scrub plant community in the western portion of the project site near Gabbert Road during the April 2018 tree survey. Since some basal growth was observed on the burned walnut trees following the 2006 fire in 2009, this is likely the result of post-fire regrowth. The tree clump was just beginning to leaf out for the season and appeared to be in good health. It likely coincides with the tree numbered 92 on the Rincon tree survey map (Figure 3). Every effort should be made to protect this native California tree during project implementation.

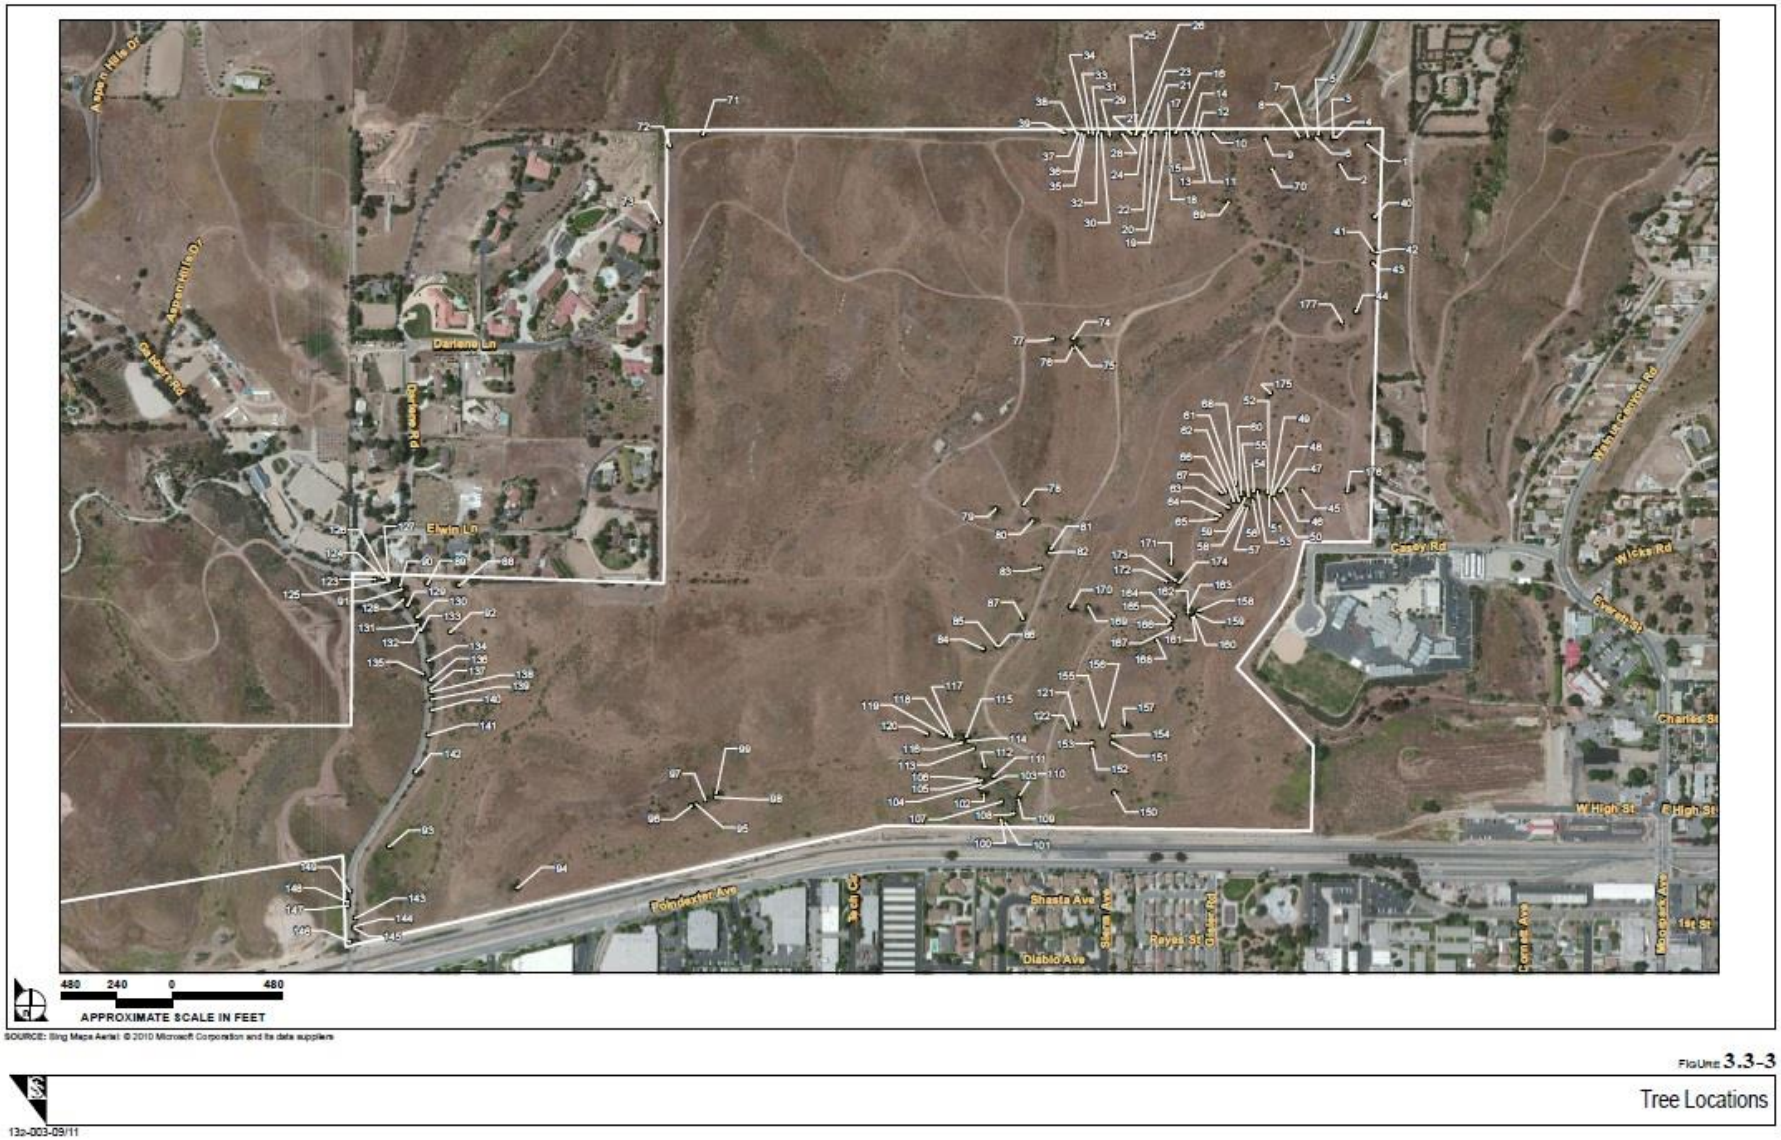

Figure 3. Rincon 2011 Tree Survey Map of the Hitch Ranch Project Site

Locally Protected Trees

Mature non-native trees, which are of local special interest, are present on the site. The City of Moorpark tree ordinance (under Chapter 12.12 Historic Trees, Native Oak Trees And Mature Trees 14.09.010—14.09.140, [12.12] No. 101) provides for the protection of all species of mature trees with a cross-sectional area of all major stems of 72 or more square inches, as measured at 4.5 feet above the root crown. As previously stated, the original tree survey was conducted on the site in 1995 (Nature Buffs). A total of 528 trees were observed during the survey that qualified as mature trees, including gum, pepper, olive (*Olea europaea*), ash (*Fraxinus* sp.), tamarisk (*Tamarix* sp.), African sumac (*Rhus lancea*), and walnut. Most of these trees were affected by the 2003 and 2006 fires. Those on the interior of the site were completely burned, but many of the trees that line the edge of the site were only partially burned and many have since recovered.

The 2018 survey reassessed the presence and health of remaining mature trees using the numbering system and mapping of a thorough tree survey conducted in 2011 by Rincon (Figure 3). These data are presented in Table A2 of Appendix 2. Survey results indicate that 143 mature trees remain alive and therefore still qualify under the Moorpark ordinance for consideration for preservation.

Special-Status Wildlife

The DEIR concluded that 16 special-status species either utilize or could potentially utilize the project site, and 12 of these species had the potential for significant impacts to some portion of their life history upon project implementation. The DEIR proposed mitigation measures for the latter species. The 2009 Hitch Ranch Special-status Species Update report made additional conclusions and mitigation suggestions for seven other species that would reduce potential impacts to less than significant. This report concurs with these findings. Table 1 summarizes these conclusions and recommendations.

Table 1. Impact Conclusions for Sensitive Wildlife Species Analyzed in Past Studies and the DEIR

DEIR Analyzed Species that Utilize or Could Potentially Utilize the Project Site	**Potential Significant Impacts**	**DEIR Proposed Mitigation Measures**
Western spadefoot	Yes	Yes
Coastal whiptail	Yes	Yes
Coast horned lizard	Yes	Yes
California horned lizard	Yes	Yes
White-tailed kite	Yes	Yes
Cooper's hawk	Yes	Yes
California rufous-crowned sparrow	Yes	Yes
Loggerhead shrike	Yes	Yes
Yellow-breasted chat	No, no nesting habitat on site	NA
Sharp-shinned hawk	No, no nesting habitat on site	NA
Ferruginous hawk	No, no nesting habitat on site	NA
Northern harrier	Yes	Yes
Prairie falcon	No, no nesting habitat on site	NA
Bell's sage sparrow	Yes	Yes
California horned lark	Yes	Yes
San Diego black-tailed jackrabbit	Yes	Yes
Additional Species That Were Not Evaluated or not Anticipated to be Affected in the DEIR That May Utilize the Project Site	**Potential Impacts**	**Mitigation Measures Proposed in the 2009 Special-status Species Up-date to Address Potential Impacts**
Coast patch-nosed snake	Yes	Covered by DEIR mitigation measures
Grasshopper sparrow	Yes	Covered by DEIR mitigation measures
Burrowing owl	Yes, however mitigatable to *less than significant*	Preconstruction nesting or winter surveys and protection of occupied burrows until nestlings have fledged or wintering birds have been safely excluded from the burrows.
Costa's hummingbird	Yes	Covered by DEIR mitigation measures
Allen's hummingbird	Yes	Covered by DEIR mitigation measures
San Diego desert woodrat	Yes, however mitigatable to *less than significant*	Preconstruction focused surveys for woodrats and nests; either protection of nests or relocation of woodrats and nesting material.
American badger	Yes, however mitigatable to *less than significant*	Preconstruction focused surveys for denning sites and delay of nearby construction activities until young are weaned and leave the den.

ASACE Jurisdictional Resources

Several drainages occur throughout the site, the largest of which occurs along a sandy wash in the western portion of the site, west of Gabbert Road. A defined stream channel is not present at this location, but plant wetland-indicators grow within this sandy wash. Other drainages, including the erosional feature in the northeastern portion of the site, may qualify as USACE jurisdictional resources. Therefore, a formal wetland delineation should be conducted pursuant to USACE survey protocols and a subsequent agency jurisdictional determination made, and if applicable, impacts quantified. If part of the proposed project, the discharge of fill into USACE-jurisdictional areas would likely require a permit pursuant to Section 404 of the Clean Water Act. Any modification to a streambed if present including removal of riparian vegetation, may require a streambed alteration agreement from CDFG pursuant to Section 1602 of the *California Fish and Game Code*. The Regional Water Quality Control Board also certifies USACE Section 404 permits and regulates discharge of fill into "waters of the United States" to ensure that Section 401 Clean Water Act or waste discharge under the Porter-Cologne Act criteria are met.

Spea hammondii **Element Code:** AAABF02020

western spadefoot

Listing Status:	**Federal:**	None	**CNDDB Element Ranks:**	**Global:**	G3
	State:	None		**State:**	S3
	Other:	BLM_S-Sensitive, CDFW_SSC-Species of Special Concern, IUCN_NT-Near Threatened			
Habitat:	**General:**	OCCURS PRIMARILY IN GRASSLAND HABITATS, BUT CAN BE FOUND IN VALLEY-FOOTHILL HARDWOOD WOODLANDS.			
	Micro:	VERNAL POOLS ARE ESSENTIAL FOR BREEDING AND EGG-LAYING.			

Occurrence No.	290	**Map Index:**	55430	**EO Index:**	55430	**Element Last Seen:**	2004-04-29
Occ. Rank:	Excellent			**Presence:**	Presumed Extant	**Site Last Seen:**	2004-04-29
Occ. Type:	Natural/Native occurrence			**Trend:**	Unknown	**Record Last Updated:**	2004-05-11

Quad Summary: Moorpark (3411838)

County Summary: Ventura

Lat/Long:	34.33618 / -118.87951	**Accuracy:**	80 meters
UTM:	Zone-11 N3801032 E327106	**Elevation (ft):**	1500
PLSS:	T03N, R19W, Sec. 16 (S)	**Acres:**	0.0

Location: ALONG ROSELAND AVENUE, WEST OF HAPPY CAMP CANYON REGIONAL PARK, NORTH OF MOORPARK.

Detailed Location:

Ecological: HABITAT CONSISTS OF A MAN-MADE BASIN WHICH CREATED A POND WITH A HEAVY SILT/CLAY STRUCTURE. DRYING SEDIMENT CREATES LARGE CRACKS WHERE JUVENILE TOADS CAN BE FOUND.

General: 100'S OF TADPOLES OBSERVED ON 29 APR 2004.

Owner/Manager: PVT

Occurrence No.	332	**Map Index:**	63622	**EO Index:**	63717	**Element Last Seen:**	2000-03-XX
Occ. Rank:	Good			**Presence:**	Presumed Extant	**Site Last Seen:**	2000-03-XX
Occ. Type:	Natural/Native occurrence			**Trend:**	Unknown	**Record Last Updated:**	2006-01-09

Quad Summary: Simi (3411837)

County Summary: Ventura

Lat/Long:	34.30408 / -118.77622	**Accuracy:**	specific area
UTM:	Zone-11 N3797301 E336546	**Elevation (ft):**	1055
PLSS:	T03N, R18W, Sec. 33 (S)	**Acres:**	3.1

Location: ABOUT 2.25 MILES NE OF THE INTERSECTION OF BREA CANYON ROAD AND HIGHWAY 118, SIMI VALLEY.

Detailed Location:

Ecological: HABITAT CONSISTS OF A CATTLE POND WITHIN A GRAZED AREA DOMINATED BY ANNUAL GRASSLAND TUCKED AGAINST BASE OF FOOTHILLS DOMINATED BY COASTAL SAGE SCRUB.

General: 100'S OF TADPOLES OBSERVED DURING MAR 2000.

Owner/Manager: PVT-UNOCAL

Occurrence No.	334	**Map Index:** 63638	**EO Index:**	63733	**Element Last Seen:**	2003-04-22
Occ. Rank:	Excellent		**Presence:**	Presumed Extant	**Site Last Seen:**	2003-04-22
Occ. Type:	Natural/Native occurrence		**Trend:**	Unknown	**Record Last Updated:**	2006-01-10

Quad Summary: Simi (3411837)

County Summary: Ventura

Lat/Long:	34.30090 / -118.82267	**Accuracy:**	specific area
UTM:	Zone-11 N3797024 E332265	**Elevation (ft):**	935
PLSS:	T03N, R19W, Sec. 36 (S)	**Acres:**	2.3

Location: ABOUT 1.1 MILES NW OF THE INTERSECTION OF ALAMOS CANYON ROAD AND HIGHWAY 118, SIMI VALLEY.

Detailed Location: SITE IS LOCATED ON OPEN SPACE; MOORPARK COLLEGE IS LOCATED IMMEDIATELY TO THE SW.

Ecological: HABITAT CONSISTS OF A VERNAL POOL SURROUNDED BY OPEN, NATIVE AND ANNUAL GRASSLAND ON A GENTLY SLOPING, BROAD RIDGE.

General: 100'S OF POST-METAMORPHIC JUVENILES OBSERVED ON 22 APR 2003.

Owner/Manager: PVT-UNOCAL

Rana boylii

Element Code: AAABH01050

foothill yellow-legged frog

Listing Status:	**Federal:**	None	**CNDDB Element Ranks:**	**Global:**	G3
	State:	None		**State:**	S3
	Other:	BLM_S-Sensitive, CDFW_SSC-Species of Special Concern, IUCN_NT-Near Threatened, USFS_S-Sensitive			
Habitat:	**General:**	PARTLY-SHADED, SHALLOW STREAMS & RIFFLES WITH A ROCKY SUBSTRATE IN A VARIETY OF HABITATS.			
	Micro:	NEED AT LEAST SOME COBBLE-SIZED SUBSTRATE FOR EGG-LAYING. NEED AT LEAST 15 WEEKS TO ATTAIN METAMORPHOSIS.			

Occurrence No.	812	**Map Index:** 78717	**EO Index:**	79662	**Element Last Seen:**	1940-05-23
Occ. Rank:	Unknown		**Presence:**	Presumed Extant	**Site Last Seen:**	1940-05-23
Occ. Type:	Natural/Native occurrence		**Trend:**	Unknown	**Record Last Updated:**	2010-04-27

Quad Summary: Piru (3411847), Cobblestone Mtn. (3411857)

County Summary: Ventura

Lat/Long:	34.49162 / -118.83146	**Accuracy:**	nonspecific area
UTM:	Zone-11 N3818190 E331838	**Elevation (ft):**	2130
PLSS:	T05N, R19W, Sec. 25 (S)	**Acres:**	113.0

Location: 1.2 AIR MI STRETCH OF CREEK IN HOPPER CYN FROM 2.1 MI ENE TO 2.5 MI NE OF HOPPER MOUNTAIN, ABOUT 4 MI W OF LAKE PIRU.

Detailed Location: LOCATION STATED AS "HOPPER CR., 2 MI NE HOPPER MT.".

Ecological:

General: 11 ADULT/JUVENILES (MVZ #33664-33673; 54519) COLLECTED ON 23 MAY 1940.

Owner/Manager: USFS-LOS PADRES NF

Occurrence No.	813	**Map Index:**	78733	**EO Index:**	79673	**Element Last Seen:**	1962-06-13
Occ. Rank:	Unknown			**Presence:**	Presumed Extant	**Site Last Seen:**	1962-06-13

Subject: **Coastal California Gnatcatcher Protocol Breeding Season Survey Report for the Hitch Ranch Specific Plan Project Site, City of Moorpark, Ventura County, California**

Dear Ms. Rapista:

Rincon Consultants, Inc. (Rincon) has prepared this Coastal California Gnatcatcher (*Polioptila californica californica*; CAGN) protocol breeding season survey report to document the methods and results of protocol CAGN surveys conducted for the Hitch Ranch Specific Plan Project (Project) located within the City of Moorpark, Ventura County, California. The required notification to conduct focused surveys was submitted by email to the permit coordinator at the Ventura U.S. Fish and Wildlife Service (USFWS) Office dated May 11, 2021 (Attachment 1).

Project Location and Survey Area

The proposed Project is in southeastern Ventura County between the Simi Hills and Little Simi Valley (Attachment 2, Figure 1). Specifically, the 277.30-acre project site is located within the *Moorpark, California* USGS 7.5-minute topographic quadrangle, Township 3 North, Range 19 West, San Bernardino Baseline and Meridian USGS 2021. The CAGN Survey Area consists of approximately 40 acres of suitable CAGN habitat of the total 277.30 acres (Attachment 2, Figure 2). The Survey Area is located at elevations ranging between 475-695 feet above mean sea level.

Project Description

The proposed Project is designed as a mixed-density community in southeastern Ventura County in the City of Moorpark, between the Simi Hills and Little Simi Valley. The Project provides for the arrangement of various land uses on the 277.30-acre project site. Proposed land uses include several types/intensities of residential land uses, a neighborhood park site, and flood-control facilities. Other improvements include storm drains, water mains, sanitary sewer lines, electric lines, natural gas lines, and telephone and cable lines.

Vegetation Communities within the Survey Area

The project site consists of 11 vegetation communities or land covers and include annual brome grassland, annual brome grassland (disturbed/grazed), blue elderberry stands, blue elderberry stands (disturbed/grazed), California sagebrush-deerweed scrub, California sagebrush-deerweed scrub (disturbed/grazed), cactus scrub (disturbed/grazed), chaparral yucca scrub (disturbed/grazed), developed, disturbed/disced, and non-native woodland (disturbed/grazed) (Attachment 2, Figure 3). Of these, only California sagebrush-deerweed scrub and California sagebrush-deerweed scrub (disturbed/grazed) are considered suitable habitat for CAGN and together comprise the 40-acre Survey Area. Representative photographs are presented in Attachment 3.

California Sagebrush-Deerweed Scrub (*Artemisia californica-Lotus scoparius* Shrubland Alliance)

Remnant patches of the California sagebrush-deerweed community, which together total 39.13 acres, occur in the western portion of the project site. There is 26.21 acres of this community to the west of Gabbert Road that is relatively undisturbed; whereas 12.92 acres of this community located to the east of Gabbert Road is substantially disturbed by ongoing cattle grazing and other disturbances that have occurred (e.g., fires and agriculture). The vegetation within this community on the east-side of Gabbert Road is sparce and generally stunted from ongoing long-term cattle grazing and drought conditions. These disturbances have limited regeneration and natural recruitment from occurring. The overstory of the California sagebrush-deerweed community is dominated by California sagebrush (*Artemisia californica*) and deerweed (*Acmispon glaber*), which forms a nearly uniform stand within the plant community. Occasional individuals of coyote brush (*Baccharis pilularis*), sawtooth goldenbush (*Hazardia squarrosa*), coast prickly-pear (*Opuntia littoralis*), and giant wildrye (*Elymus condensatus*) occur within this community, along with a few blue elderberry (*Sambucus nigra* ssp*. caerulea*), chaparral yucca (*Hesperoyucca whipplei*), and non-native Peruvian pepper (*Schinus molle*). The understory is composed of non-native grasses.

This community contains poor quality suitable habitat for CAGN, with low species diversity and low abundance of California sagebrush. The majority of the Survey Area was burned by the Rye Fire in 2017 and is currently recovering from the fire, with deer weed occurring as an early successional species.

Survey Methodology

The CAGN surveys described by this report were conducted in accordance with the *Coastal California Gnatcatcher (Polioptila californica californica) Presence/Absence Survey Guidelines, February 1997* (USFWS); hereafter referred to as the "protocol."

Focused breeding season surveys were conducted by federal 10(a)(1)(A) permitted Rincon biologist Kelly Rios (TE-018909-5) during the 2021 breeding season. A total of six surveys, at least 7 days apart, were conducted between May 26 and June 30, 2021. Surveys were conducted between 0815 and 1200, when weather conditions were favorable (no excessive heat, fog, wind, rain, cold). Survey dates, times, and weather conditions are listed in Table 1.

Surveys consisted of slowly walking linear transects throughout the Survey Area, stopping at approximate 50-foot intervals to play an audio recording of CAGN vocalizations. Binoculars were used to

aid in observing habitat for CAGN and other avian species. The recording was played for several seconds at each interval followed by a brief pause to listen for a response. If any CAGNs were observed, the age, sex, breeding status, and behavioral characteristics were documented, when possible.

Table 1 Coastal California Gnatcatcher Survey Conditions and Results

Date	Biologist	Beginning Conditions	Ending Conditions	CAGN Observed
May 26, 2021	Kelly Rios	0815; 70°F, winds 1-2 mph, 0% clouds	1200; 73°F, winds 3- 5 mph, 0% clouds	Yes
June 2, 2021	Kelly Rios	0830; 62F, winds 1-2 mph, 0% clouds	1200; 75°F, winds 1-2 mph, 00% clouds	Yes
June 9, 2021	Kelly Rios	0800; 60°F, winds 1-2 mph, 40% clouds	1200; 72°F, winds 2-3 mph, 20% clouds	Yes
June 16, 2021	Kelly Rios	0900; 83°F, winds 1-2 mph, 40% clouds	1200; 87°F, winds 2-3 mph, 10% clouds	Yes
June 23, 2021	Kelly Rios	0940; 69°F, winds 2-3 mph, 10% clouds	1200; 87°F, winds 2-7 mph, 0% clouds	Yes
June 30, 2021	Kelly Rios	1000; 74°F, winds 1-2 mph, 0% clouds	1200; 78°F, winds 2-3 mph, 0% clouds	No

Survey Results

The project site consists of rolling hills and is dominated by annual brome grassland vegetation community. Although the California sagebrush-deerweed scrub onsite provides suitable habitat for CAGN, the majority is considered to be poor quality vegetation community. Due to the many years of active cattle grazing onsite, the species density and diversity is very low. Native plants sparsely occur within the community. The tops of many of the plants have been grazed on by cattle. The southwestern portion of the project site, west of Gabbert Road, contains moderate quality California sagebrush-deerweed scrub. No cattle grazing occurs in this portion of the site and the native plants occur in higher density and species diversity.

Despite the poor-quality habitat onsite, coastal California gnatcatchers were observed during 5 of the 6 surveys (Table 1). During the first survey, one pair of CAGN was observed in the northwest portion of the project site within California sagebrush-deerweed scrub. This was the only time this pair was observed during the six surveys. An additional pair was also observed along the northern boundary during the first survey. This pair was most likely nesting in the habitat to the north of the project site. They were also observed during the 2nd-4th surveys and remained in the suitable habitat to the north of the project site. Coastal California gnatcatcher observations are presented in Attachment 2, Figure 3.

A single female or possible juvenile CAGN was observed in the central portion of the project site during the 3rd survey. The CAGN initially responded vocally to the audio recording and then flew further to the southwest and was undetected.

During the 5th survey, a single female or possible juvenile CAGN was observed in the northcentral portion of the project site in a small area containing California sagebrush. This CAGN only responded a couple of times to the recording and then flew to the north.

It is unclear if these sightings were the same CAGN or different individuals. During both observations of the single CAGNs, the birds remained very low in the California sagebrush. They were relatively quiet and were not displaying behaviors of defending a territory. Therefore, these individual sightings of CAGN could possibly be dispersing juveniles from the pair of CAGNs located north of the project site. Most likely they were foraging in the project site, rather than using the California sagebrush as nesting habitat.

No CAGN were detected within the moderate quality California sagebrush-deerweed scrub located in the southwestern portion of the project site.

Avian activity during the protocol surveys was relatively low throughout the surveys. Bird species observed or otherwise detected during surveys include species commonly found in upland scrub habitats such as, but not limited to, California towhee (*Melozone crissalis*), house finch (*Haemorphous mexicanus*), lesser goldfinch (*Spinus psaltria*), Anna's hummingbird (*Calypte anna*), and Bewick's wren (*Thryomanes bewickii*). Attachment 3 provides a complete list of avian species detected or observed in the Survey Area during the protocol CAGN surveys.

One additional sensitive species, southern California Rufous-crowned sparrow (*Aimophila ruficeps canescens*) was observed during the surveys and is on CDFW Watch List. Brown-headed cowbirds (*Molothrus ater*), considered to be nest parasites for CAGNs, were not observed during the surveys. Bird species detected during the surveys are presented in Attachment 4.

Thank you for the opportunity to work with you on this Project. Please contact Greg Ainsworth if you have questions concerning the contents of this report. He may be reached by telephone at 805-465-9091, or by email at gainsworth@rinconconsultants.com.

Sincerely,
Rincon Consultants, Inc.

USFWS Survey Notification

May 11, 2021
Project No: 21-11432

Chris Kofron
Ventura Fish and Wildlife Office
U.S. Fish and Wildlife Service
2493 Portola Road, Suite B
Ventura, California 93003

Subject: Notification of Intent to Conduct Protocol Breeding Season Surveys for Coastal California Gnatcatcher for the Hitch Ranch Specific Plan Project, City of Moorpark, Ventura County, California

Dear Mr. Kofron,

In accordance with the current U.S. Fish and Wildlife Service (USFWS) survey protocol for coastal California gnatcatcher (*Polioptila californica californica*; CAGN) (dated February 28, 1997), please consider this letter as notification of the intent to commence protocol breeding season surveys on behalf of Comstock Homes for the Hitch Ranch Specific Plan Project (project), in the City of Moorpark, Ventura County, California. The proposed project is in southeastern Ventura County between the Simi Hills and Little Simi Valley (Figure 1). Specifically, the project site is located within the *Moorpark, California* USGS 7.5-minute topographic quadrangle, Township 3 North, Range 19 West, San Bernardino Baseline and Meridian (USGS 2020a) (Figure 2).

The proposed project is designed as a mixed-density community and provides for the arrangement of various land uses on the 277.30-acre project site. Proposed land uses include several types/intensities of residential land uses, a neighborhood park site, and flood-control facilities. Other improvements include storm drains, water mains, sanitary sewer lines, electric lines, natural gas lines, and telephone and cable lines.

Kelly Rios, a Section 10(a)(1)(A) permitted biologist (TE 018909-5) with Rincon Consultants, Inc. (Rincon) will conduct all the CAGN surveys. According to Hitch Ranch Project 2018 Biological Survey Update (Barringer Biological Services, 2018), approximately 40 acres of the total 277.30 acres is comprised of California sagebrush-deerweed scrub, which is considered suitable habitat for CAGN. This habitat, as well as a 500-foot surrounding buffer, together comprise the survey area. The surveys will follow USFWS Coastal California Gnatcatcher Presence/Absence Survey Guidelines, issued July28, 1997 (USFWS 1997). The first survey is scheduled following the 15-day period, on May 26, so thatthe subsequent five surveys
will be completed by the end of the CAGN breeding survey season, June 30.

Sincerely,

Greg Ainsworth, MCRP, Natural Resources Director

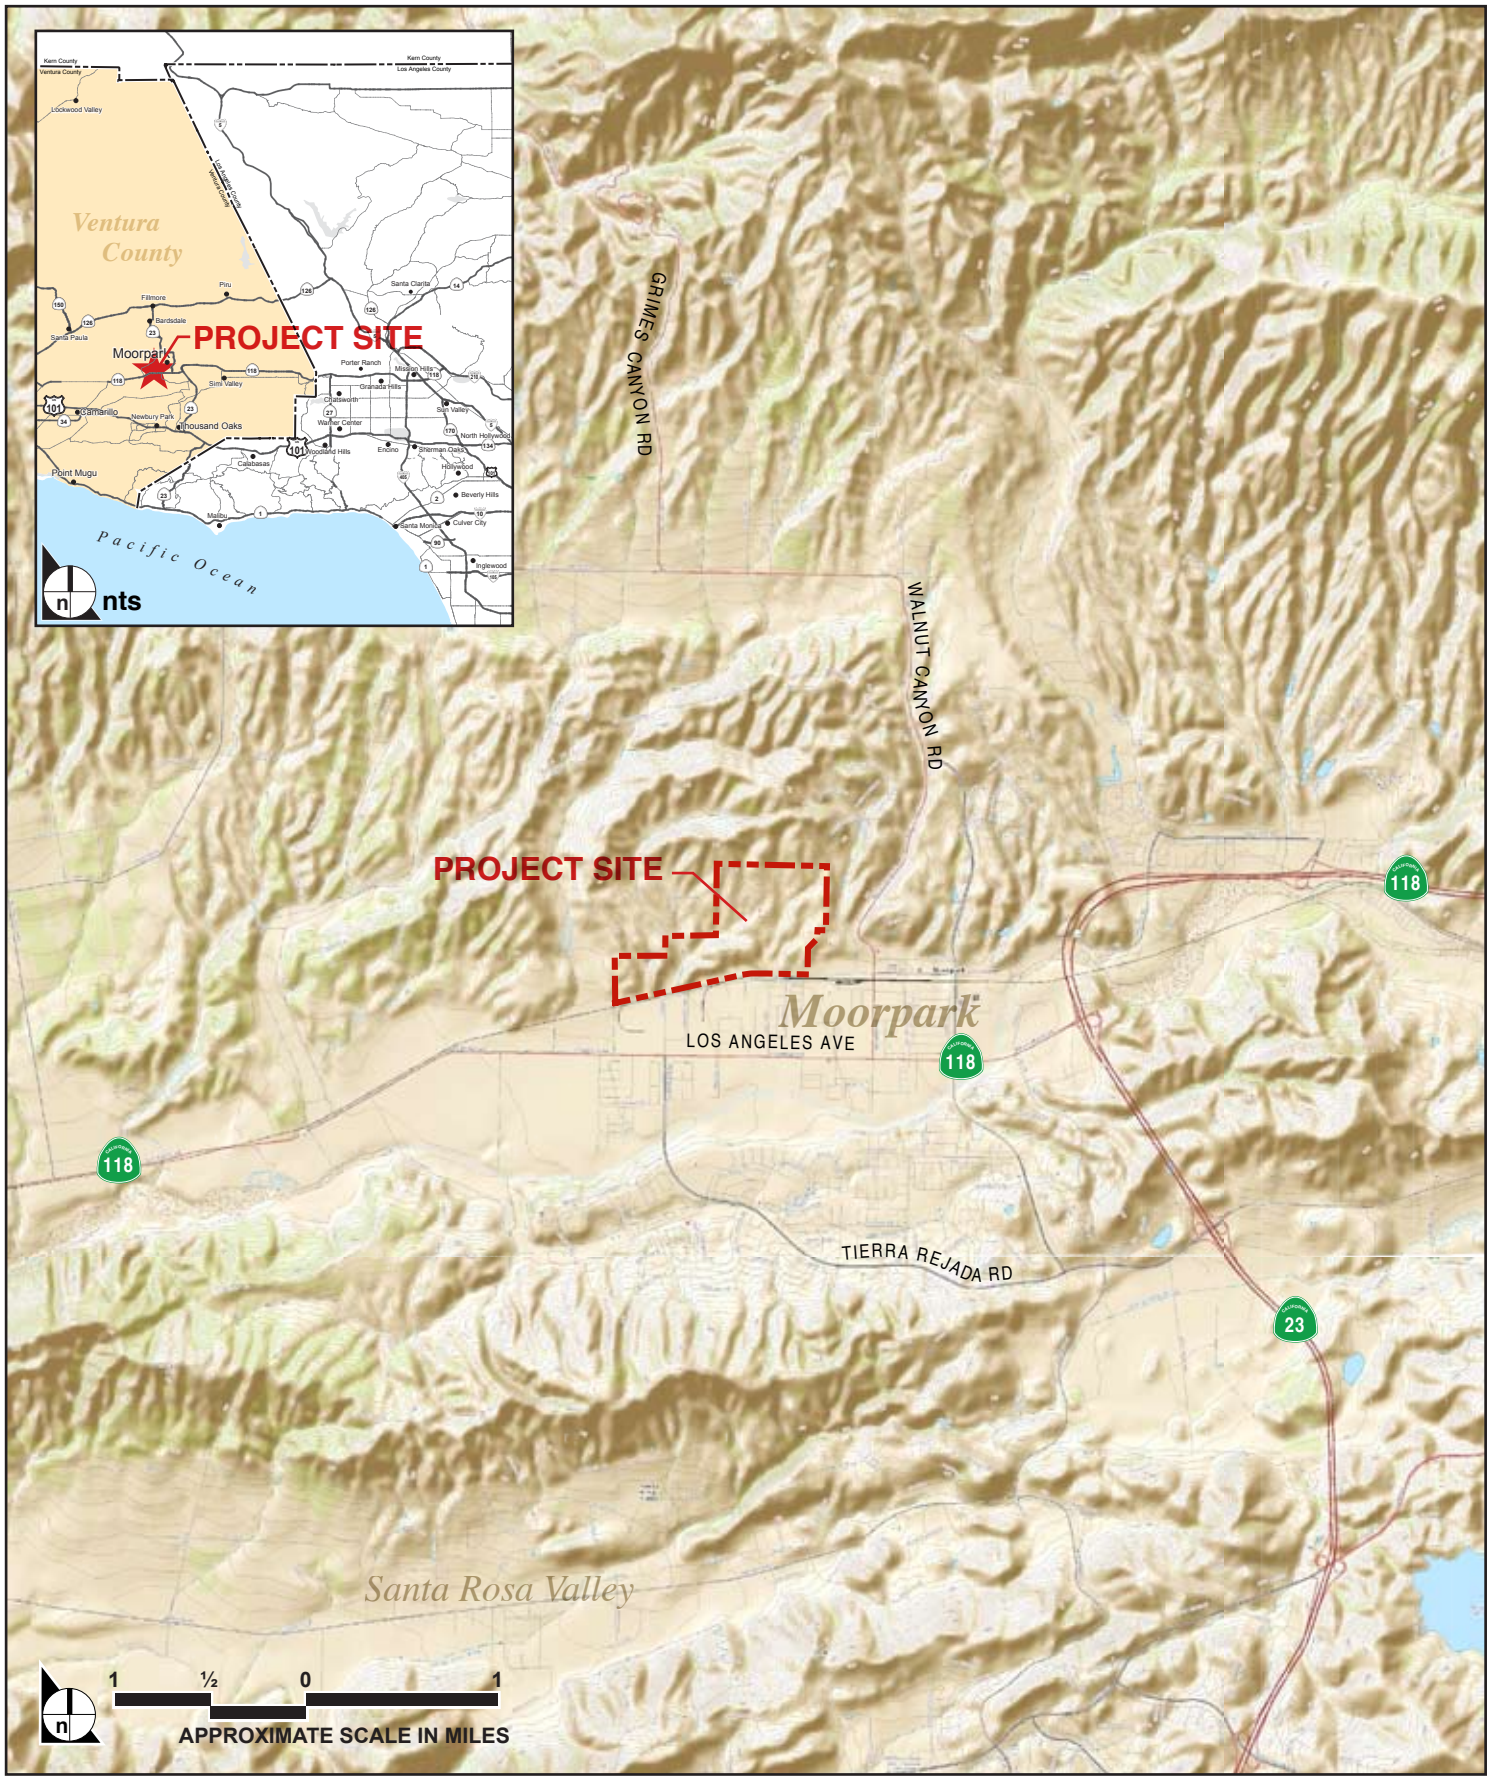
Re: Results of Focused California Gnatcatcher Surveys; Hitch Ranch Project; Moorpark, CA



Dear Mr. Kofron:

The purpose of this letter report is to provide the US Fish and Wildlife Service, the City of Moorpark and Development Planning Services with the methodology and findings of surveys for the federally-listed Threatened California gnatcatcher (*Polioptila californica*) (herein CAGN) conducted by Dave Crawford (Permit #TE-821229-7) of Impact Sciences on the Hitch Ranch project site in Moorpark, California (**Figure 1**). The surveys were conducted for the purpose of determining the presence or absence of CAGN within the study area.

BACKGROUND

Projects have been proposed on this site multiple times and entitlements were initiated in 1993. Since then there have been multiple biological surveys, including focused CAGN surveys in 1998, 2000, 2003, 2005, 2009, and 2011. All surveys were negative with the exception of 2000, when a single juvenile was detected during one of the survey dates.

Wildfires occurred on the site in 2003 and again in 2009 which significantly changed the vegetation associations on site. Early surveys on the site documented over 80 acres of coastal sage scrub and coyote brush scrub. Currently there is just over 20 total acres of coastal sage scrub left on the site, which occurs primarily on the western portion of the site on relatively steep slope. There is very little coyote brush scrub left as well. Mostly non-native grasses and annual herbaceous species have taken over the areas of burned out scrub habitats leaving just scattered shrubs.

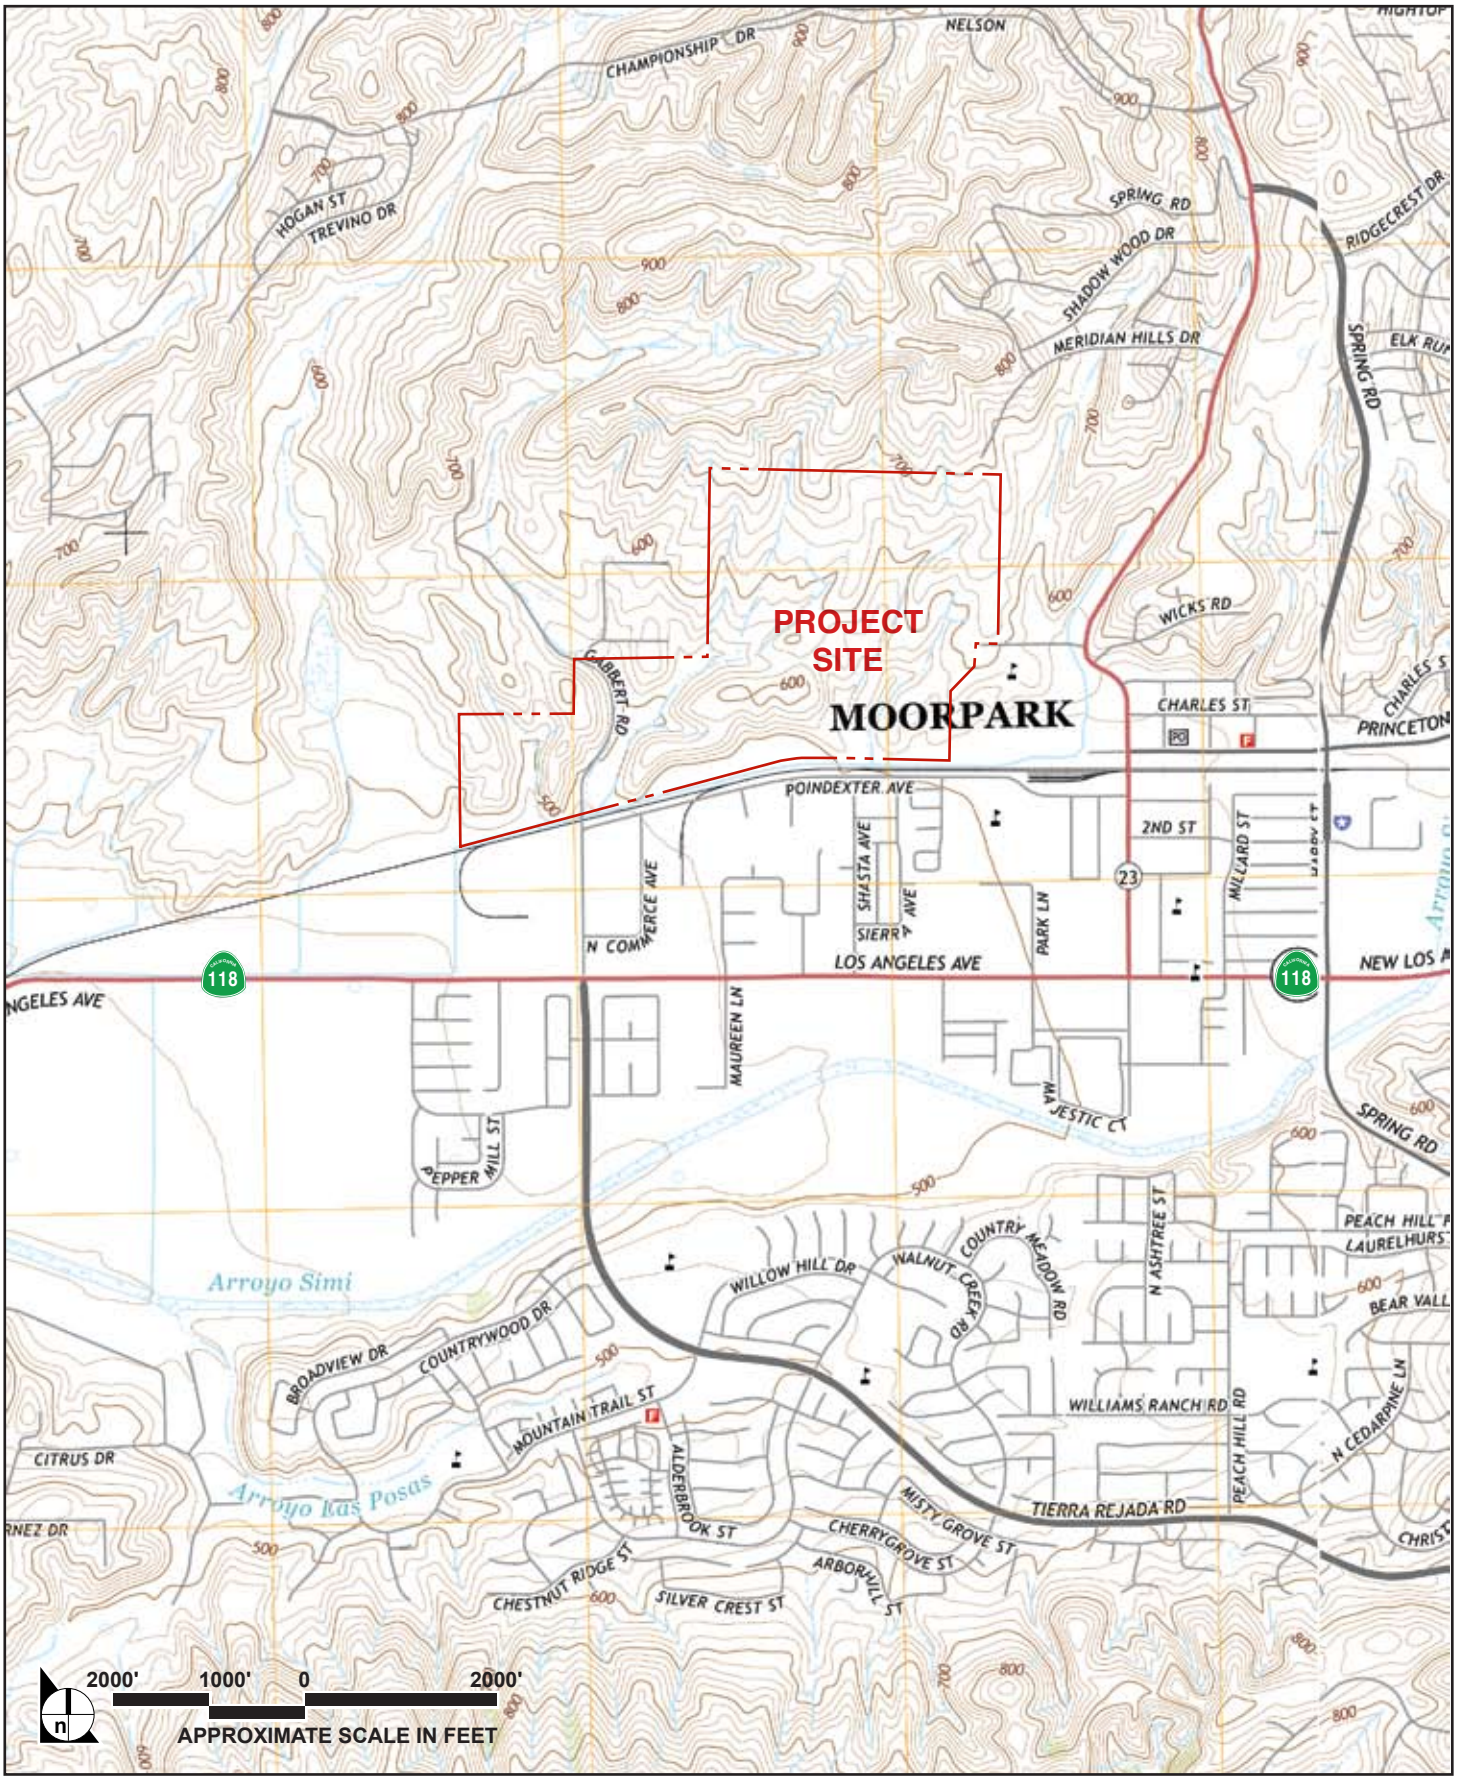
IMPACT SCIENCES

Regional Location and Vicinity

132.03•04/16



LOCATION

The project site is located in the City of Moorpark, CA. It is situated at the southern limit of the Simi Hills, between the Oak Ridge Mountains to the north and the Las Posas Hills to the south. The project is situated at T2N, R19W, in Sections 5 and 6 of the Moorpark, California USGS 7.5-minute quadrangle map (**Figure 2**).

SITE DESCRIPTION

The subject property totals approximately 283 acres and supports less than 20 acres of coastal sage scrub habitat; most of which occurs on steep slopes in the western portion of the site. It is characterized by a series of north-south trending ridges, gently rolling hills, and shallow valleys. The topography ranges from moderately steep to relatively flat, and is highly varied. The site has been previously disturbed, primarily due to historic agricultural activities, and a major wildfire in 2006 scorched the site, eliminating much of the scrub vegetation. Currently vegetation on the site consists primarily of annual grassland vegetation, with scattered small patches of coastal sage scrub, coyote brush and woodland vegetation communities; mostly eucalyptus. Foundations of a few old structures and numerous dirt roads are still present on the site. Elevation at the site ranges from approximately 475 to 720 feet above mean sea level.

Land uses surrounding the project site include a few single family homes and the Walnut Canyon Elementary School are located immediately east, and the City of Moorpark downtown area is located about one-quarter of one mile further to the east. A mixture of institutional, residential and light industrial uses occurs to the south. Single family homes and farmland are located to the west. Undeveloped hills are located to the north. A Ventura County Flood Control District concrete flood control channel (Walnut Canyon Channel) borders the site to the south. The Southern Pacific Railway tracks border the flood channel. A narrow strip of flat, vacant land separates the tracks from Poindexter Avenue, a two-lane arterial between Moorpark Avenue on the east and Gabbert Road to the west.

METHODOLOGY

Surveys were initiated March 17, 2016, following notification to the Ventura USFWS field office. Based on the seasonal timing, it was determined that six focused surveys, conducted at least seven days apart, would be appropriate to determine presence/absence of CAGN on the Hitch Ranch project site. Mr. Dave Crawford conducted the series of surveys under the authority of his own Section 10(a)1(A) Endangered Species Recovery permit.

The surveys were performed March 17, 24, 31, April 7, 14 and 21, 2016. Surveys were focused in areas supporting the coastal sage scrub associations, as well as surrounding buffers of approximately 200 feet. All appropriate habitat areas were systematically surveyed on foot by walking slowly and methodically along random transect routes. The locations of each transect and survey points were based on the vegetation and topographic conditions (size, location, and shape of habitat) of the area to be surveyed to ensure complete coverage. Calling points were separated by approximately 200-foot intervals, or as needed, depending upon the vegetation and topography in each area. A combination of digitally recorded vocalizations (played at 30 to 60 second increments) and "pishing" sounds were used at each calling point.

Due to the relatively clear weather conditions, surveys were generally conducted between 6:45 a.m. and 11:00 a.m. Weather during the surveys was conducive to a high level of bird activity. Temperatures varied from approximately 52 degrees Fahrenheit in the mornings to a maximum of about 75° F at the end of the survey day. Wind speed ranged from 0 to 10 mph and skies ranged from completely overcast to sunny during the six surveys.

RESULTS

No California gnatcatchers were observed or detected during any of the six surveys conducted on site. A total of 56 avian species was observed or detected. Avian species observed included six that are on the California Department of Fish and Wildlife "Special Animals List."[1] There were also four non-native introduced species observed.

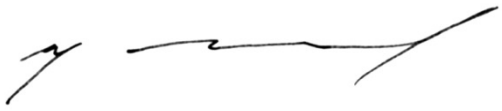
---

[1] California Department of Fish and Wildlife, Natural Diversity Database. April 2016. Special Animals List. Periodicpublication.51 pp.

Special-status species observed included Cooper's hawk, rufous hummingbird, Allen's hummingbird, Nuttall's woodpecker, oak titmouse, and lark sparrow. A complete list of all bird species identified on the project site during the survey efforts is included as **Attachment A**.

Prior to the surveys, Dave Crawford communicated with Chris Dellith of the USFWS Ventura Field office. Mr. Dellith provided Mr. Crawford with results from 2015 gnatcatcher surveys in the project vicinity indicating California gnatcatcher had been recorded from adjacent properties east and northwest of the Hitch Ranch site. One report also identified an occurrence within the Hitch Ranch boundaries near the north central border. During the surveys, Mr. Crawford spent considerable time at or near each of the previously reported occupied locations. Vegetation on the Hitch Ranch site was not typical of what is considered suitable gnatcatcher habitat, but off site there were some higher quality habitats. In the western portion of the site, the more common blue-gray gnatcatcher (*Poliptila caerulea*) was observed and heard on two occasions, but there were no indications of the presence of California gnatcatcher.

Based on the previously submitted reports of CAGN occurring on and adjacent to Hitch Ranch, it was expected that CAGN would be observed or detected during the surveys. As such, Mr. Crawford had Ron Francis, Jr. accompany him. Mr. Francis is also permitted to survey CAGN, but did not participate in an 'official' status as he did not play recordings, make "pishing' noises or disturb any habitat. He simply accompanied Mr. Crawford to serve as a second set of eyes and ears in hopes of detecting CAGN. Neither biologist saw or heard any indication of CAGN.



Numerous avian species were observed copulating, and displaying other pairing and nesting behaviors. Four separate pairs of red-tailed hawk were observed on site with at least two pairs actively building nests. It was also interesting to note that an American badger (*Taxidea taxus*), a California species of special concern, was observed during one of the surveys running along a dirt road with a freshly killed California ground squirrel in its mouth. This was interesting as badger had never been documented on site during any of the previous biological surveys and three was no record for this species in the California Natural Diversity DataBase (CNDDB) in the vicinity.

Additionally a few stick nests, attributable to woodrats, were observed on site. Both the common big-eared woodrat (*Neotoma macrotus*) and the CDFW species of special concern San Diego desert woodrat (*Neotoma lepida intermedia*) are known to occur in the area and either can build or utilize stick nests so positive identification cannot be made on the observation of stick nests alone.

CONCLUSIONS

Based on the results of six surveys following USFWS survey protocol methods there were no CAGN present on the Hitch Ranch project site in spring 2016. Because there are records of their occurrence on and adjacent to the site in 2015, it is uncertain why they would not be present this year. Habitat within the Hitch Ranch boundaries is not as suitable as other properties near it, and this survey effort did not include other properties, but since there were multiple pairs and juveniles observed last year, one would expect that one or more would at least have been detected near the project site where they had been previously recorded.

Sincerely,
Impact Sciences, Inc.

E

2011 Gnatcatcher Survey

compliance•biology inc

September 2, 2011

Mr. Mark Austin
Impact Sciences, Inc.
803 Camarillo Springs Road
Suite A
Camarillo, California 93012

Subject: Results of Focused Coastal California Gnatcatcher Surveys; Hitch Ranch Property; Moorpark, California

Dear Mr. Austin,

This letter report summarizes the methodology and findings of surveys for the federally-listed Threatened California gnatcatcher (*Polioptila californica*) (herein CAGN) conducted by Compliance Biology, Inc. on a project site in the City of Moorpark, Ventura County, California. The surveys were conducted for the purpose of determining the presence or absence of CAGN within the study area.

PROPERTY DESCRIPTION

The subject property totals approximately 283 acres and supports about 15 acres of marginally suitable coastal sage scrub habitat. The project site is located on the north side of Poindexter Road and the Southern Pacific railway, west of SR 23 in the City of Moorpark, Ventura County, California. Gabbert Road runs approximately north-south through the western portion of the site. The survey location is situated at T2N, R19W, on portions of Sections 5 and 6 of the Moorpark, California U.S.G.S. 7.5-minute quadrangle map (**Exhibit 1**). The subject property is characterized by variable topography with a dry drainage feature traversing the site from north to south adjacent and east of Gabbert Road. Elevation at the project site ranges from approximately 480 feet to approximately 720 feet above mean sea level.

Existing residential, institutional and urban development occurs northeast, east and south of the site. Properties to the north and west are undeveloped and rural residential respectively.

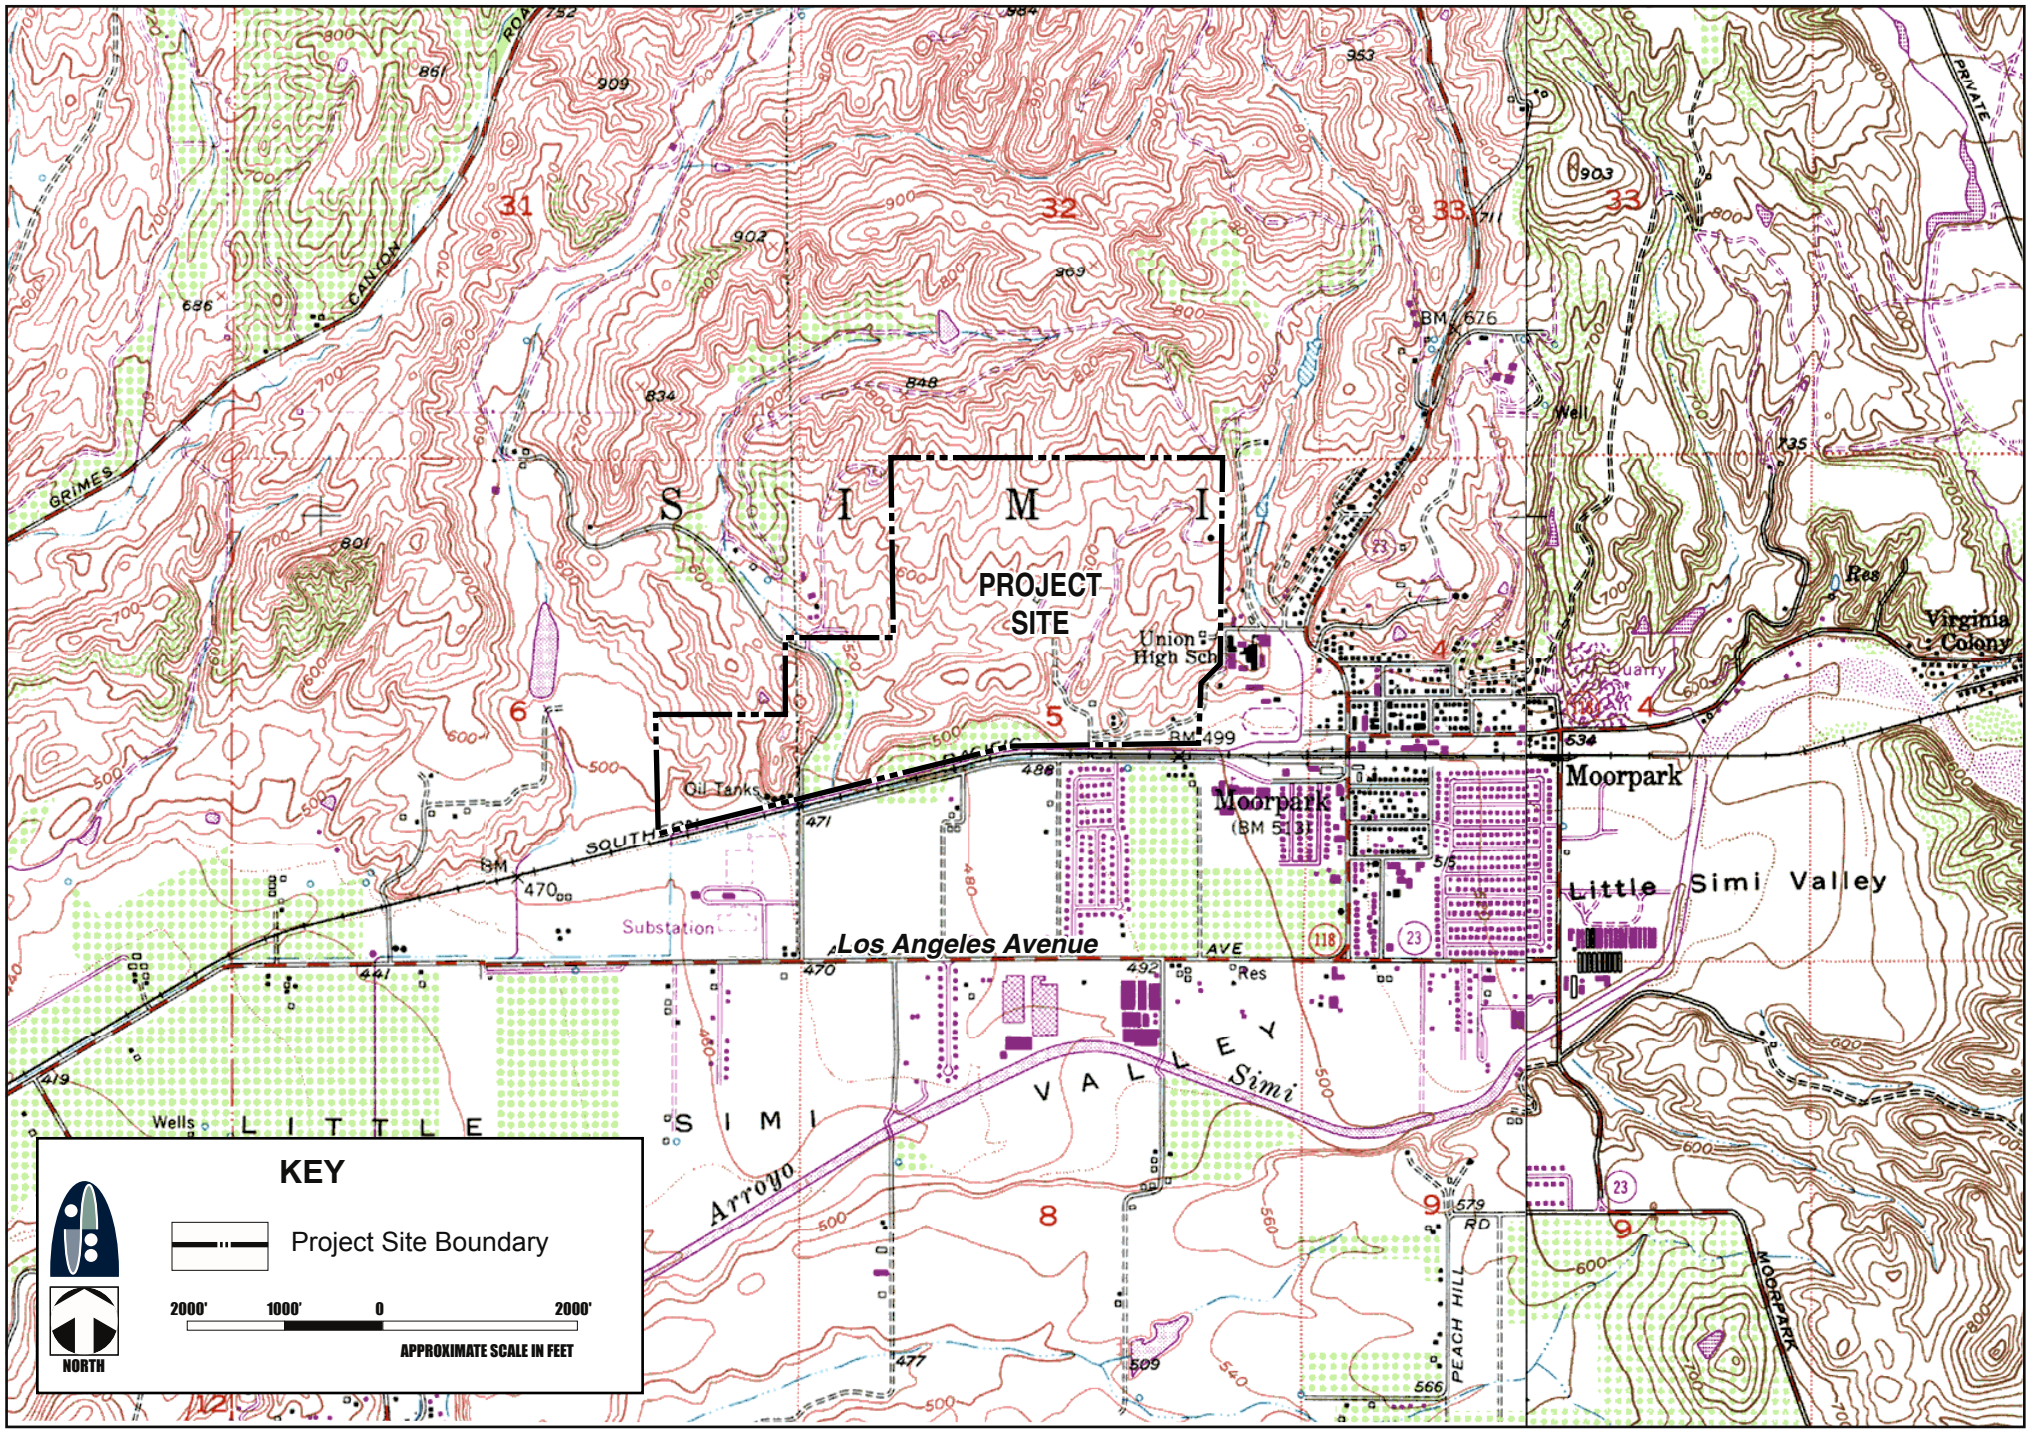

exhibit **1**

PROJECT LOCATION U.S.G.S. 7.5 MINUTE QUADRANGLE

VEGETATION

Nearly the entire subject property was burned during the brush fires of fall 2003. Previously, nine separate plant associations had been identified within the project boundaries. Of these, six had elements of scrub habitats potentially suitable for California gnatcatcher. Now, most of the site is characterized as ruderal or non-native annual grassland with a few areas supporting elements of remnant California coastal sage scrub. Almost all of the sage scrub habitat occurring on the site is new growth, with dense mustard (*Hirschfeldia incana*) and non-native grasses (*Avena*, *Bromus*, etc.) still dominating.

METHODOLOGY

Service recommended survey guidelines stipulate a minimum of six surveys shall be conducted at least one week apart between March 15 through June 30, and from July 1 through March 14, a minimum of nine surveys shall be conducted at least two weeks apart. Guidelines also recommend that surveys be completed between 6:00 a.m. and 12 p.m.; that they shall avoid periods of inclement weather or excessive heat, rain, wind, and fog; and the rate of coverage should be no more than 80 acres per day per permitted biologist.

Based on the aforementioned guidelines, the seasonal timing of initiation of these surveys and discussion with Mr. Chris Dellith of the US Fish and Wildlife Service Ventura Field office, a total of eight (8) focused surveys were conducted within and adjacent to potentially suitable on-site coastal scrub habitats. Seven-day intervals between site visits were utilized for the first three (3) surveys in June and 14-day intervals were utilized for the remaining five (5) surveys. All field surveys were performed by David Crawford under the authority of his individual Endangered Species Recovery Permit.

Surveys were conducted on June 6, 13, 20, July 4, 18, and August 1, 15, and 29 2011. Approximately 20 acres of potentially suitable scrub habitat and a surrounding buffer zone into adjacent habitats were surveyed each day. All potential habitat areas were systematically surveyed on foot by walking slowly and methodically along random transect routes. The location of transects and survey points along each transect were based on the vegetation and topographic conditions

(size, location, and shape of habitat) of the area to be surveyed to ensure complete coverage. A combination of taped vocalizations (played at 30-60 second increments) and "pishing" sounds were used at each calling point.

Weather conditions during the surveys were clear and warm and generally conducive to a high level of bird activity. All surveys were conducted between the hours of about 7:00 a.m. and approximately 11:00 a.m. Temperatures varied from approximately 55 degrees Fahrenheit (F) to a maximum of about 80F. Wind speed ranged from 0 to 10 mph during the surveys and typically averaged less than 5 mph. Cloud cover varied from overcast to completely clear.

RESULTS

A total of 40 avian species was observed or detected on the subject property. No California gnatcatchers or any other federal or state-listed endangered, threatened, or candidate species were observed on site during the survey effort. A complete list of all vertebrate species observed during the survey efforts is included as **Attachment A**.

One avian species considered to be of special-status was observed during three of the surveys. Loggerhead shrike (*Lanius ludovicianus*) is considered a California Species of Special Concern (SSC) and a US Fish and Wildlife Service Bird of Conservation Concern (BCC). Both the SSC and BCC statuses indicated the regulatory agencies' goal to draw attention of those species that are declining with the hopes of promoting greater study and habitat protection for these species.

A single loggerhead shrike was observed on three of the survey dates. The bird was seen at the same perch each time, suggesting it is likely a resident on or near the subject property.

DISCUSSION

This series of surveys for CAGN was the sixth conducted on the site. Surveys following Service protocol guidelines were also completed in 1998, 2000, 2003, 2005 and 2009. In 2000 a single juvenile CAGN was observed on a single occasion. It was concluded at that time that it was likely dispersing from the known occupied site situated approximately one mile east of the subject property, and was not a resident of the site. No CAGN have been observed or detected during any other survey conducted on site. Conditions on the Hitch Ranch project site have changed considerably since 2003 as a result of the brush fires that occurred on site. These

changes have significantly reduced the potential habitat for CAGN. Based on the results this and past protocol surveys, it is concluded that CAGN are not currently present on site, nor are they expected to occur in the near future. As such, this species would not be significantly impacted by any proposed development.

As discussed, a loggerhead shrike was observed on site and is expected to be a resident. The SSC and BCC statuses afforded this species do not provide legal protection. Notwithstanding, project impacts to animals with these designations must be considered when that project undergoes CEQA review.

Further, although none of the individual birds observed are afforded protection under the state or federal endangered species acts, most of the avian species observed are protected under the California Fish and Game Code and the Federal Migratory Bird Species Treaty Act (1985) while actively nesting. As such, grading and/or any other activity resulting in the removal of vegetation should be conducted outside the typical nesting season (February 1 through August 30). Should such activities be required during this period of time, it is recommended that nesting bird surveys be conducted consistent with Service and California Department of Fish and Game guidelines.

Thank you for the opportunity to provide Impact Sciences with continued biological services. Please feel free to contact me if you have any questions regarding the contents of this report.

Sincerely,

Dave Crawford

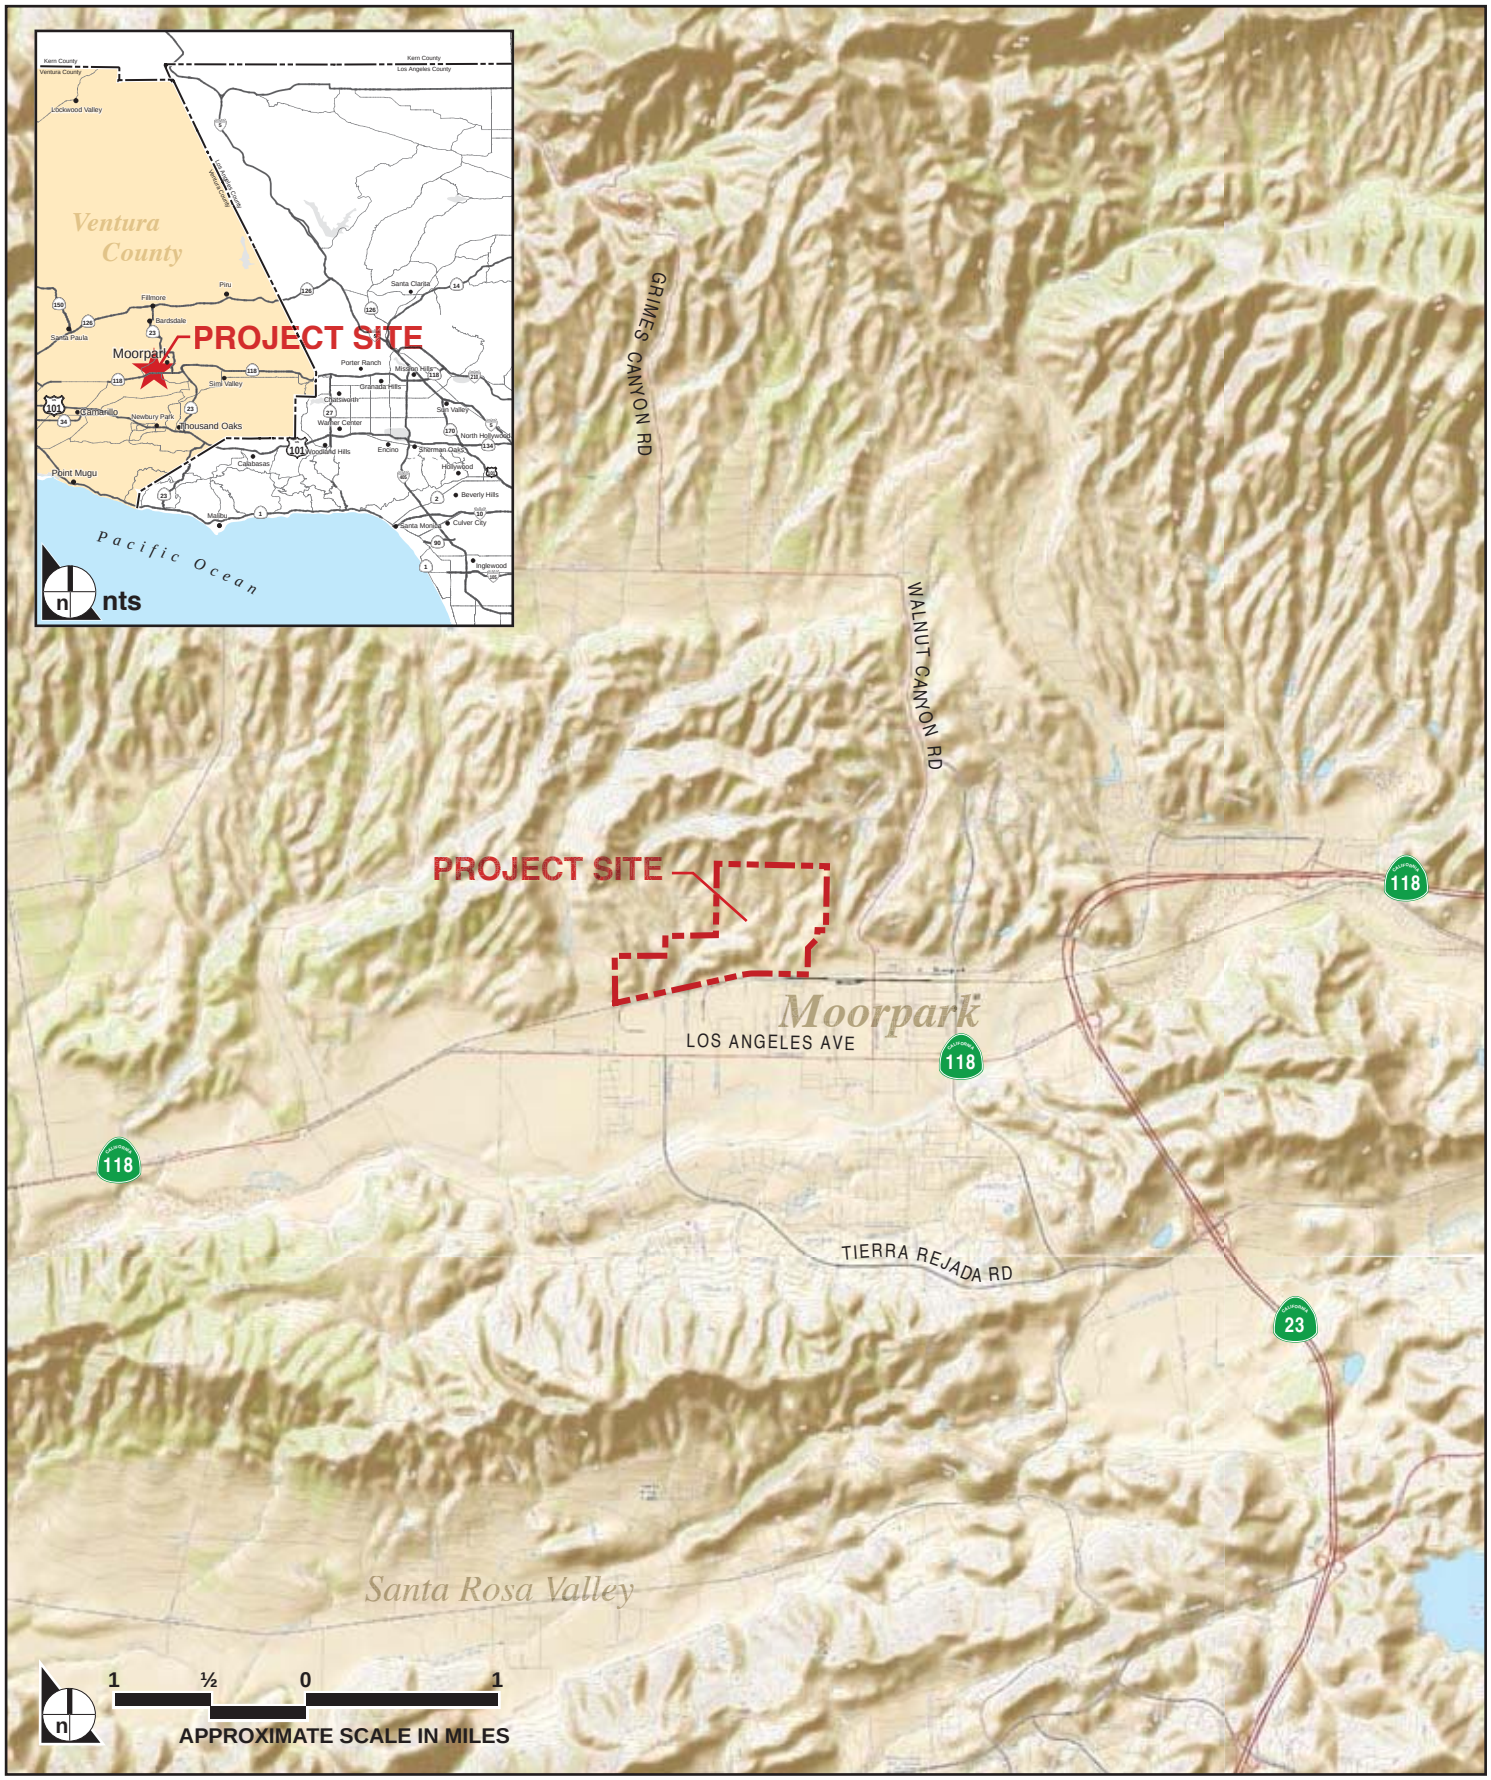
Appendix B Observed Flora

INTRODUCTION & SCOPE

This report provides the results of three focused plant surveys conducted in the spring of 2016 of the Hitch Ranch project site, located in the city of Moorpark, Ventura County, California (Figure 1, Regional Location and Vicinity). These surveys searched for special status plant species previously reported as occurring within a nine quadrangle area including and surrounding the 283-acre project site.

The goal was to search for special status plants within the proposed project site. Special-status plants are those listed by the state of California or the Federal Government as Endangered, Threatened, or Rare or are candidates for such listing,[1] and species listed by the California Native Plant Society (CNPS) with a Rare Plant Rank of 1, 2, or 3.[2]

Location & Existing Conditions



The Hitch Ranch property is located within the Transverse Ranges at the southern limit of the Simi Hills, between the Oak Ridge Mountains to the north and the Las Posas Hills to the south. The property is situated at T2N, R19W, in Sections 5 and 6 of the Moorpark, California USGS 7.5-minute quadrangle map. Regionally, the project site is located in southeastern Ventura County between the Simi Hills and Little Simi Valley. Locally, the project site is located in the rolling hills north of Poindexter Avenue and west of Moorpark Road (State Route 23) and Walnut Canyon Elementary School. The property is located approximately 1,600 feet west of State Route 23, and extends approximately 1,400 feet west of Gabbert Road.

The property contains variable topography, with generally north-south trending ridgelines separated by level to gently sloping valleys. Elevations range from 475 to 720 feet. Vegetative cover is dominated by non-native annual grasslands, with areas of coastal sage scrub and numerous non-native trees, primarily gum (*Eucalyptus* spp.) and pepper (*Schinus* spp.) trees.

Previous disturbances include historic agricultural activities and wildfires, the latter including fires as recently as 2003, 2006 and 2009. Several well-used dirt roads and trails crisscross the property, with indications of equestrian, bicycle, off-road vehicle and pedestrian use. Old foundations evidenced by concrete rubble are present near the southern boundary of the property.

METHODS

Literature Search

The California Natural Diversity Database[3] and California Native Plant Society Inventory of Rare and Endangered Plants[4] were searched prior to field surveys to identify previously reported special status plant occurrences in the project vicinity. Nine 7.5-minute US Geological Survey (USGS) topographic quadrangles were searched, including for the project quadrangle (Moorpark) and the following eight adjacent quadrangles:, Santa Paula Peak, Fillmore, Piru, Santa Paula, Simi Valley, Camarillo, Newbury Park, and Thousand Oaks. Soils data was reviewed relative to the potential occurrence of substrate endemics.[5]

Field Surveys

Field surveys for were conducted by Jacqueline Bowland Worden of Impact Sciences, Inc. on March 26, April 20, and May 13, 2016. The field surveys followed protocol defined by the California Native Plant Society and California Department of Fish and Wildlife. All areas of the property were walked, and a comprehensive list of all plants was compiled (planted ornamental plants were excluded). The taxonomic reference for all species was the current Jepson Manual.[6]

RESULTS

Literature Search

Data Base Findings

The database search reported 24 special-status plant species as occurring on the Camarillo quadrangle (project site location) and the surrounding seven quadrangles (listed previously). **Appendix A** details these species, along with habitat requirements and occurrence potential on the subject property.

6 Baldwin, B.G., D.H. Goldman, D.J. Keil, R. Patterson, T.J. Rosatti, and D.H. Wilken, editors. *The Jepson Manual: Vascular Plants of California*. Second edition. University of California Press, Berkeley. 2012.

Soils Data

The two predominant soil types found within the study area were identified as containing gravelly loam to loam, with all other soils characterized as sandy loam. Many of the special status plants listed in Appendix A occur primarily on specific soil types, such as those derived from volcanic rocks, alkaline soils, ultramafic (serpentine) soils, clay-rich soils, sandstone, or granitic, rocky soils. None of those specific soil types have been identified as occurring on-site, nor were such conditions observed.

Field Surveys

One special-status plant species was observed during the spring 2016 site surveys, southern California black walnut ((*Juglans californica* var. *californica*). This tree carries a CNPS Rare Plant Rank (RPR) of 4.2, indicating plants of limited distribution (4), fairly threated in California (0.2). **Appendix B** provides a list of all plant species observed during the 2016 field surveys.

Southern California black walnut (*Juglans californica* [var. *californica*]). Several native walnut trees were found in the western area of the property, east of and within about 300 feet of Gabbert Road. These trees do not form a woodland, since they are scattered over a large area. California walnut groves (*Juglans californica* woodland alliance) have a rarity ranking of G3 S3.2, indicating this species is "vulnerable" throughout its range and "threatened" within California.

No other special status plants were found, nor have any been previously recorded as occurring on or near the site. Wildfires, and both previous and current land uses such as orchards, dirt access roads, and fuel modification for fire safety (such as disking, mowing, etc.), have resulted in a substantially reduced probability of such plants occurring on the project site.

Several special-status plant surveys have been conducted on the subject property, all with negative results (except for walnut trees). Spring surveys were completed in 1998, 2000, 2007, 2007 and 2009.

CONCLUSIONS & RECOMMENDATIONS

Native walnut trees should be avoided. A tree survey should be conducted to establish precise locations of these trees such that appropriate protection zones may be defined. No other special status plants species were detected during the 2016 focused rare plant surveys.

APPENDIX A

Special-Status Plant Species Reported From the Project Vicinity

Appendix A
Special-Status Plant Species Recorded for the Hitch Ranch Property Vicinity

March 2016 CNDDB Query for: Moorpark, Newbury Park, Santa Paula, Simi Valley West, Camarillo, Thousand Oaks, Santa Paula Peak, Fillmore, and Piru USGS Quadrangles.

Scientific and Common Name	Status			Habitat Requirements	Elevation Range, Life Form, and Flowering Period	Potential Occurrence
	Federal	State	CNPS			
Abrams' oxytheca *Acanthoscyphus parishii var. abramsii*	--	--	1B.2	Sandy flats and slopes in chaparral and montane conifer woodlands. Known locally only from Topatopa Mountain and Mount Pinos.	1610-2010m AH June-Aug	**Not Expected**: The site is too low in elevation and does not contain suitable substrates.
Braunton's milk-vetch *Astragalus brauntonii*	E	--	1B.1	Recent burns or disturbed areas, usually sandstone with carbonate layers, in chaparral, coastal scrub valley and foothill grassland, closed-cone coniferous forest.	4-640m PH January-August	**Not Expected**: Substrate endemic: no suitable habitat on-site: not present.
Round-leaved filaree *California macrophylla*	-	-	1B.1	Cismontane woodland/valley & foothill grassland on clay soils.	15-1200m AH March-May	**Not Expected:** Suitable grassland habitat may be present but is densely vegetated with non-native plants and does not appear to be clay-rich.
Late-flowered mariposa lily *Calochortus fimbriatus*	--	--	1B.2	Sandy loams on alluvial fans on serpentine	350-1250m PH June- Aug	**Not Expected:** This species is a substrate endemic on serpentine soils. Reported sightings are from 2007 and earlier, at higher elevations.
Southern tarplant *Centromadia parryi ssp. australis*	--	--	1B.1	Salt marshes, vernal pools, freshwater wetlands, moist valley grassland and coastal sage scrub.	0-440m AH May-Nov	**Not Expected:** This species usually occurs in wetlands but occasionally found in non-wetlands (facultative wetland plant). Suitable conditions are not present on-site.
Santa Susana tarplant *Deinandra minthornii*	--	R	1B.2	Chaparral, coastal scrub/ rocks on Santa Susana sandstone substrates.	280-760m. S July-November	**Not Expected:** This species is a substrate endemic: suitable Santa Susana sandstone soils are not present on-site.
Dune larkspur *Delphinium parryi ssp. blochmaniae*	--	--	1B.2	Coastal dunes and chaparral.	20-120m PH April-May	**Not Expected:** Typically found on the coast in sandy habitats. The only Ventura County report is from 1969; other sightings are much farther north.
Umbrella larkspur *Delphinium umbraculorum*	--	--	1B.3	Foothill woodland	460-1450m PH April - June	**Not Expected:** Suitable habitat is not present on the site. Most recent record (2010) from Matilija Canyon.
Blochman's dudleya *Dudleya blochmaniae* ssp. *blochmaniae*	-	-	1B.1	Chaparral, coastal bluff scrub, ultramafic, valley and foothill grassland with coastal influence. Open, rocky slopes, often serpentine or clay-dominated.	7-550m PH April-June	**Not Expected:** No suitable serpentine or clay soils/substrates on-site. No dudleyas were found on-site.
Marcescent dudleya *Dudleya cymosa ssp. marcescens*	T	-	1B.2	Chaparral, cismontane woodland: open rocky volcanic slopes	<460m PH May-June	**Not Expected:** Endemic to volcanic substrates; there are no volcanic soils or substrates on the site.

Scientific and Common Name	Status			Habitat Requirements	Elevation Range, Life Form, and Flowering Period	Potential Occurrence
	Federal	State	CNPS			
Conejo dudleya *Dudleya parva*	T	--	1B.2	Rocky or gravelly, clay or volcanic. Coastal scrub, valley and foothill grassland.	60-450m PH May-June	**Not Expected:** Endemic to volcanic substrates; there are no volcanic soils or substrates on the site.
Verity's dudleya *Dudleya verityi*	FT	--	1B.2	North-facing volcanic outcrops.	60-120m PH May-June	**Not Expected:** Endemic to volcanic substrates; there are no volcanic soils or substrates on the site.
Conejo buckwheat *Eriogonum crocatum*	--	R	1B.2	Conejo volcanic outcrops, rocky. Chaparral, Coastal scrub, valley and foothill grassland.	50-580 PH April-July	**Not Expected:** Endemic to volcanic substrates; there are no volcanic soils or substrates on the site.
Ojai fritillary *Fritillaria ojaiensis*	--	--	1B.2	Rocky slopes, river basins in partial shade.	300-500m PH(b) Feb-May	**Not Expected: S**uitable habitat is not present.
Mesa horkelia *Horkelia cuneata var. puberula*	--	--	1B.1	Sandy or gravelly soils in maritime chaparral, cismontane woodland and coastal scrub.	40-1110m PH Feb-Sept	**Not Expected:** Suitable habitat is not present.
Ross' pitcher sage *Lepechinia rossii*	--	--	1B.2	Chaparral.	570-1130m S May-Sept	**Not Expected:** Suitable habitat is not present. All reports in Ventura Co. are from the southern slope of Topatopa Mtn, north of Fillmore.
White-veined monardella *Monardella hypoleuca ssp. hypoleuca*	--	--	1B.1	Saline places, vernal pools or moist areas in and adjacent to riparian habitats.	<1000m AH April-May	**Not Expected:** No suitable mesic or riparian habitat is present on site.
Gerry's curly-leaved monardella *Monardella sinuata ssp. gerryi*	--	--	1B.1	Sandy soils, coastal strand, dune and sagebrush scrub, coastal chaparral and oak woodland	150-245m AH April-Sept	**Not Expected:** Suitable habitats are not present.
Ojai navarretia *Navarretia ojaiensis*	--	--	1B.1	Grasslands; openings is chaparral and coastal scrub; on clay soils.	300-1000m AH May-July	**Low potential:** Clay soils are not present, and none were found.
Chaparral nolina *Nolina cismontana*	--	--	1B.3	Oak woodland, chaparral.	<1500m PH June-August	**Low Potential:** Suitable substrates are present; however, this distinctive plant was not found.
California Orcutt grass *Orcuttia californica*	E	E	1B.1	Vernal pools.	15–660m AH April–August	**Not Expected**: No vernal pool habitat is present.
Lyon's pentachaeta *Pentachaeta lyonii*	E	E	1B.1	Grasslands and openings in chaparral of coastal mtns with heavy and/or clay soils.	200-1300m AH April-July	**Not Expected:** Soils on-site are not clay rich; limited suitable habitat is present. The survey timing would have detected this plant if present.
White rabbit tobacco *Pseudognaphalium leucocephalum*	--	--	2B.2	Sandy, gravelly soils in chaparral, cismontane woodland, coastal scrub and riparian woodland.	PH July-Dec	**Not Expected:** Soils do not appear to be suitable. Most reports are older than 20 years.

Scientific and Common Name	Status			Habitat Requirements	Elevation Range, Life Form, and Flowering Period	Potential Occurrence
	Federal	State	CNPS			
Chaparral ragwort *Senecio aphanactis*	--	--	2B.2	Alkaline endemic in chaparral, coastal sage scrub and woodlands.	10-550M AH Jan-April	**Not Expected:** Alkaline soils are not present on the site
Greata's aster *Symphyotrichum greatae*	--	--	1B.3	Broadleaf upland forest, chaparral, cismontane woodland, lower montane coniferous forest, riparian woodland.	300-2010m PH(r) June-Oct	**Not Expected:** Suitable habitat is not present. Reported north of South Mountain in a different watershed.

STATUS KEY:

Federal

FE: Federally Endangered

FT: Federally Threatened Species

FC: Federal Candidate Species

SC: Species of Concern: An informal term that refers to species considered to be in need of concentrated conservation actions.

State

SE: State Endangered
SR: State Rare

CNPS California rare plant ranks

1A: Plants presumed extirpated in California and either rare or extinct elsewhere
1B: Plants rare, threatened, or endangered in California and elsewhere
2A: Plants presumed extirpated in California, but common elsewhere
2B: Plants rare, threatened, or endangered in California, but more common elsewhere
3: Plants about which more information is needed – a review list
4: Plants of limited distribution – a watch list.

Threat Ranks

0.1: Seriously threatened in California (over 80% occurrences threatened/high degree and immediacy of threat
0.2: Moderately threatened in California (20-80% occurrences threatened/moderate degree and immediacy of threat.
0.3: Not very threatened in California (less than 20% of occurrences threatened/ low degree and immediacy of threat or no current threats known.

COPYRIGHT NOTICE
This Document is owned by and is the Sole and Exclusive Property of L. NEWMAN DESIGN GROUP, INC. All Information Contained in this Document is for the Use on the Specified Project and Shall Not be Used/Copied Without the Expressed Written Permission of L. NEWMAN DESIGN GROUP, INC.

OBJECTIVES

The objective of this report is to qualify the present condition of the site's trees and to discuss the potential encroachments to them. This involved:

1. Determining the physiological condition of each tree;
2. Ascertaining the encroachments that will occur due to grading (see site plan/**TREE LOCATION MAP)**;

METHODS OF STUDY

Qualification of this site's trees was accomplished by the use of our standard visual survey, as completed by L. NEWMAN DESIGN GROUP, INC. (**LNDG**) in December of 2020 in accordance with the City of Moorpark Municipal Code Title 12, Chapter 12.12, Historic Trees, Native Oak Trees, and Mature Trees. In the course of the fieldwork, we performed the following:

1. Tree trunks were measured at 4½' above mean natural grade;
2. The trees were tagged with numbered, metal tags. These tags were affixed to the sides of the trees and correspond to the numbers on the **TREE LOCATION MAP**;
3. All of the inventoried trees were located by LNDG on a topographic map/site plan (scale: 1" = 60') prepared by Encompass consultant Group. Refer to the **TREE LOCATION MAP** included herein for the approximate tree locations.

TREE SPECIES

Nearly all of the trees on this site are either blue gums (36 per cent) or Peruvian pepper trees (55 per cent). The blue gums were historically planted for agricultural purposes and have become naturalized. The pepper trees are a common landscape plant and also have become naturalized.

The 2 dominant species on this site and other species present are included on the 410 - Prohibited Plant List (April 2019) published by the Ventura County Fire Protection District. Refer to the Appendix in this report that contains this list which is a list of plants that the Ventura County Fire Department recommends be removed or thinned in Defensible Spaces and Fuel Modification Zones as they define them. The species of trees present on the subject site are:

Qty	Species	Common Name
1	*Cupressus sp.*	Cypress*
98	*Eucalyptus globulus*	Blue gum*
3	*Eucalyptus vimiinalis*	White gum*
1	*Pinus species*	Pine tree*
2	*Rhus lancea*	African sumac
19	*Sambucus mexicana*	Elderberry
146	*Schinus molle*	Peruvian pepper tree*
1	*Ulmus parvifolia*	Chinese elm
5	*Washingtonia robusta*	Mexican fan palm*
6	*Juglans californica*	California black walnut
282		

*Trees that are included on the Ventura County Fire Protection District, 410-Prohibited Plant List.

In comparing the results of this report to the 2019 biological survey, there appear to be 2 discrepancies in the mature tree total but they are not significant. There are approximately 30 fewer mature eucalyptus trees in this report due to the difficulty of distinguishing multiples trunks that are arranged in the windrows. Arborists may differ whether a tree has multiple trunks or the multiple trunks are individual trees. Also, there may have been some mortality of the eucalyptus between the two surveys. There are over 100 mature pepper trees in this report as compared to the 2019 survey which counted 32 mature pepper trees but over 200 immature pepper trees, most of which were badly burned a few years ago. The discrepancy in the mature tree count may be explained by the growth that occurred between the dates of the field work for each study. The pepper trees that burned to stumps prior to both surveys have sprouted new, fast-growing stems since. The definition of a mature tree includes the cumulative square inches of the individual stems. Therefore, multiple small stems can add up to the total square inches required to be considered mature. The increased stem diameter may explain why they were considered immature in 2019 and mature in 2020. All of the walnut trees were finally determined to be *Juglans californica.* The previous study noted one *Juglans nigra* but we now know that it is a *Juglans californica*.

TREE PROTECTION GUIDELINES

The City of Moorpark Zoning Ordinance provides for the protection of certain species of trees, defined as "Protected Trees": in Ordinance 101, Chapter 14.09 - Preservation, Cutting, and Removal of Historical Trees, Native Oak Trees and Mature Trees; and in Ordinance 102, Chapter 14.08 - Planting and Maintenance of Trees, Shrubs and Plants.

Ordinance 101, Section 14.09.101 - Intent and Purpose - It is the determination of the Moorpark City Council that proper and necessary steps should be taken in order to protect and preserve, to the greatest extent possible, mature trees, native Oak trees and historic trees, especially where such trees are associated with proposals for urban development, as such trees are a significant, historical, aesthetic and valuable ecological resource. It is the intent to maintain and enhance the general health, safety and welfare of the citizens of the City by assisting in counteracting air pollution, by minimizing soil erosion and other related environmental damage and by enhancing the aesthetic environment of the City.

Ordinance 102, Section 14.08.101 - Intent and Purpose - Consistent with Chapter 14.09 regulating the preservation, cutting and removal of historic trees, native Oak trees and mature trees and Resolution No. 88-520 setting forth Guidelines for a Master Tree Plan, it shall be the City's policy to utilize whatever techniques, methods and procedures are required to preserve, whenever feasible, all trees in the City including, but not limited to, trees which are creating damage to surface improvements or underground facilities or which are diseased, or located where construction is being considered or will occur.

TREES OF CONCERN

Historical Tree - Any tree or group of trees identified by the City as a landmark, or identified on the Federal or California Historic Resources Inventory to be of historical or cultural significance or identified as contributing to a site or structure of historical or cultural significance.

Mature Tree - All trunks of any tree shall be measured at 4½'. If the trunk of any oak tree trunk exceeds 4 inches in diameter or if the trunk of any other tree species exceeds 9½ inches in diameter, it is to be included in the inventory. Regrowing stumps are not to be included.

Native Oak Tree - Is any living tree of the genus *Quercus* and of the species *agrifolia*, *berberidifolia*, *dumosa*, *lobata* or hybrids thereof.

RESULTS OF STUDY

1. **Physiological Condition of the Trees**

    a. The physiological condition of each tree is shown in the **FIELD OBSERVATION SHEETS**. Nearly all of the trees were damaged in the fire that swept through this area roughly 15 to 20 years ago. Many appear to have been burned to the ground and have re-sprouted from the stumps. Half of the trees are multiple-trunk, Peruvian pepper trees that have become naturalized in southern California. Many of the pepper trees that are on the site are under size and are not a part of this inventory. Although pepper trees make good ornamental trees in cultivated landscapes, they are considered invasive species in the native landscape. Almost half of the trees are blue gums (eucalyptus trees) that are also considered an invasive species in California.

    b. A numerous native tree-like shrub is the California elderberry. Although 19 of the larger ones were included in this inventory, the other numerous, multi-stemmed ones were not. They are not true trees and were not given an appraised value.

2. **Summary of Data/Plan Review**

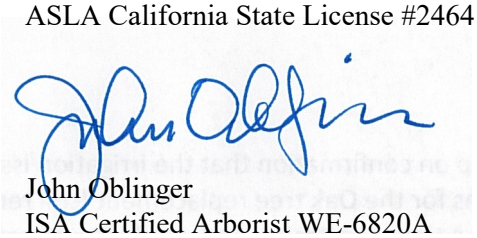
    a. All of the mature trees included in this inventory will be removed. Most of the trees will be removed due to their locations within the limit of grading. All of the eucalyptus trees and pepper trees will removed because they are on the 410-Excluded Plant List. they are invasive and tend to naturalize in southern California

    b. A circle for each tree is shown on the **TREE LOCATION MAP** to graphically represent its approximate crown spread. The trees were not precisely land surveyed but were accurately located by LNDG based on the topographic survey plan.

3. **Tree Appraisals**

    a. The replacement value of each inventoried tree was established by using the 9th Edition of the *Guide for Plant Evaluation*, as prepared for the International Society of Arboriculture by the Council of Tree and Landscape Appraisers.

b. Refer to the appendix for the appraised value of each tree using the standard trunk formula method including trunk diameter, tree species, health, aesthetics and location.



c. The total value of all of the trees as of the date of this report is $558,738.

NOTICE OF DISCLAIMER:

This report represents the independent opinion of the signatory consultant (L. NEWMAN DESIGN GROUP, INC.). The tree(s) discussed herein was/were generally reviewed for physical, biological function and aesthetic conditions. This examination was conducted in accordance with presently accepted industry procedures, which are a ground-plane macro-visual observation only. No extensive micro-biological, soil-root excavations, upper crown examination nor internal tree investigations were conducted and therefore, the reporting herein reflects the overall visual appearance of the tree(s) on the date reviewed and no warranty is implied as to the potential failure, health or demise of any part or of whole of any tree described in the report. Records may not remain accurate after our inspection due to unknown causes of changeable deterioration of the reviewed site.

Respectfully submitted,

PROHIBITED PLANT LIST

VENTURA COUNTY FIRE PROTECTION DISTRICT
FIRE PREVENTION BUREAU
165 DURLEY AVENUE
CAMARILLO, CA 93010
www.vcfd.org
Office: 805-389-9738 Fax: 805-388-4356

410 – PROHIBITED PLANT LIST

This list was first published by the VCFD in 2014. It has been updated as of April 2019. It is intended to provide a list of plants and trees that are not allowed within a new required defensible space (DS) or fuel modification zone (FMZ). It is highly recommended that these plants and trees be thinned and or removed from existing DS and FMZs. In certain instances, the Fire Department may require the thinning and or removal.

This list was prepared by Hunt Research Corporation and Dudek & Associates, and reviewed by Scott Franklin Consulting Co, VCFD has added some plants and has removed plants only listed due to freezing hazard. Please see notes after the list of plants.

For questions regarding this list, please contact the Fire Hazard reduction Program (FHRP) Unit at 085-389-9759 or FHRP@ventura.org

Prohibited plant list:Botanical Name	Common Name	Comment*
Trees		
Abies species	Fir	F
Acacia species (numerous)	Acacia	F, I
Agonis juniperina	Juniper Myrtle	F
Araucaria species (A. heterophylla, A. araucana, A. bidwillii)	Araucaria (Norfolk Island Pine, Monkey Puzzle Tree, Bunya Bunya)	F
Callistemon species (C. citrinus, C. rosea, C. viminalis)	Bottlebrush (Lemon, Rose, Weeping)	F
Calocedrus decurrens	Incense Cedar	F
Casuarina cunninghamiana	River She-Oak	F
Cedrus species (C. atlantica, C. deodara)	Cedar (Atlas, Deodar)	F
Chamaecyparis species (numerous)	False Cypress	F
Cinnamomum camphora	Camphor	F
Cryptomeria japonica	Japanese Cryptomeria	F
Cupressocyparis leylandii	Leyland Cypress	F
Cupressus species (C. fobesii, C. glabra, C. sempervirens,)	Cypress (Tecate, Arizona, Italian, others)	F
Eucalyptus species (numerous)	Eucalyptus	F, I
Juniperus species (numerous)	Juniper	F
Larix species (L. decidua, L. occidentalis, L. kaempferi)	Larch (European, Japanese, Western)	F
Leptospermum species (L. laevigatum, L. petersonii)	Tea Tree (Australian, Tea)	F
Lithocarpus densiflorus	Tan Oak	F

Prohibited plant list:Botanical Name	Common Name	Comment*
Melaleuca species (M. linariifolia, M. nesophila, M. quinquenervia)	Melaleuca (Flaxleaf, Pink, Cajeput Tree)	F, I
Olea europea	Olive	I
Picea (numerous)	Spruce	F
Palm species (numerous)	Palm	F, I,
Pinus species (P. brutia, P. canariensis, P. b. eldarica, P. halepensis, P. pinea, P. radiata, numerous others)	Pine (Calabrian, Canary Island, Mondell, Aleppo, Italian Stone, Monterey)	F
Platycladus orientalis	Oriental arborvitae	F
Podocarpus species (P. gracilior, P. macrophyllus, P. latifolius)	Fern Pine (Fern, Yew, Podocarpus)	F
Pseudotsuga menziesii	Douglas Fir	F
Schinus species (S. molle, S. terebenthifolius)	Pepper (California and Brazilian)	F, I
Tamarix species (T. africana, T. aphylla, T. chinensis, T. parviflora)	Tamarix (Tamarisk, Athel Tree, Salt Cedar, Tamarisk)	F, I
Taxodium species (T. ascendens, T. distichum, T. mucronatum)	Cypress (Pond, Bald, Monarch, Montezuma)	F
Taxus species (T. baccata, T. brevifolia, T. cuspidata)	Yew (English, Western, Japanese)	F
Thuja species (T. occidentalis, T. plicata)	Arborvitae/Red Cedar	F
Tsuga species (T. heterophylla, T. mertensiana)	Hemlock (Western, Mountain)	F
Groundcovers, Shrubs & Vines		
Acacia species	Acacia (except dwarf/prostrate variety)	F
Adenostoma fasciculatum	Chamise	F
Adenostoma sparsifolium	Red Shanks	F
Agropyron repens	Quackgrass	F, I
Anthemis cotula	Mayweed	F, I
Arbutus menziesii	Madrone	F
Arctostaphylos species	Manzanita. Also note that Eastwood Manzanita grows to 8'	F
Arundo donax	Giant Reed	F, I
Artemisia species (A. abrotanium, A. absinthium, A. californica, A. caucasica, A. dracunculus, A. tridentata, A. pynocephala)	Sagebrush (Southernwood, Wormwood, California, Silver, True tarragon, Big, Sandhill)	F
*Atriplex species (numerous)***	Saltbush	F, I**
Avena fatua	Wild Oat	F
Baccharis pilularis	Coyote Bush	F
Bambusa species	Bamboo	F, I
Bougainvillea species	Bougainvillea	F, I, FR
Brassica species (B. campestris, B. nigra, B. rapa)	Mustard (Field, Black, Yellow) Wild Turnip	F, I

Prohibited plant list:Botanical Name	Common Name	Comment*
Bromus rubens	Foxtail, Red brome	F, I
Bromus carinatus	California brome	Grows to 5', Dies if cut
Castanopsis chrysophylla	Giant Chinquapin	F
Cardaria draba	Hoary Cress	I
Carpobrotus species	Ice Plant, Hottentot Fig	I
*Ceonothus griseus " Louis Edmunds***	Louis Edmunds Ceanothus	Grow higher than 18"*
*Ceonothus griseus var. horizontalis***	Carmel Creeper Ceonothus	Grows higher than 18"**
*Ceonothus griseus var. horizontalis "yankee point"**	Yankee Point Ceonothus	Grows higher than 18"**
*Ceonothus megacarpus***	Big pod ceonothus	Grows higher than 18"**
Cirsium vulgare	Wild Artichoke	F,I
Codariocalyx motorius	Telegraph Plant	F
Conyza bonariensis	Horseweed	F
Coprosma pumila	Prostrate Coprosma	F
Cortaderia selloana	Pampas Grass	F, I
Cytisus scoparius	Scotch Broom	F, I
Delosperma "alba"	White trailing Ice Plant	F
Dodonaea viscosa	Hopseed Bush	F
Drosanthemum Floribundum	Rosea Ice plant	F
Eriodictyon californicum	Yerba Santa	F
Eriogonum species (E. fasciculatum)	Buckwheat (California)	F
Fremontodendron species	Flannel Bush	F
Hedera species (H. canariensis, H. helix)	Ivy (Algerian, English)	I
Helix Canariensis	English Ivy	F
Heterotheca grandiflora	Telegraph Plant	F
Hordeum leporinum	Wild barley	F, I
Jasminum humile	Italian Jasmine	F
Juniperus species	Juniper	F
Lactuca serriola	Prickly Lettuce	I
Lamprathus aurantiacus	Bush Ice Plant	F
Lamprathus spectabilis	Trailing Ice Plant	F
Larix species (numerous)	Larch	F
Larrea tridentata	Creosote bush	F
Lepidium virginicum	Peppergrass	F
Leymus condensatus	Giant Wild Rye	Grows to 9' tall
Lolium multiflorum	Ryegrass	F, I
Lonicera japonica	Japanese Honeysuckle	F
Mahonia species	Mahonia	F
Miscanthus species	Eulalie Grass	F
Muhlenbergia species	Deer Grass	F

Prohibited plant list:Botanical Name	Common Name	Comment*
Nassella (stipa)leprida	Foothill needlegrass	Gets to 18" high. Cant cut to 4".
Nassella (stipa) pulchra	Purple needlegrass	Same comment as above
Nerium Oleander	Oleander	Toxic
Nicotiana species (N. bigelovii, N. glauca)	Tobacco (Indian, Tree)	F, I
Pennisetum setaceum	Fountain Grass	F, I
Perovskia atroplicifolia	Russian Sage	F
Phoradendron species	Mistletoe	F
Pickeringia montana	Chaparral Pea	F
Plumbago auriculate	Cape Plumbago	F
*Rhus (R. diversiloba, R. laurina, R. lentii)***	Sumac (Poison oak, Laurel, Pink Flowering)	F**. Poison oak presents a health hazard
Ricinus communis	Castor Bean	F, I
Rhus Lentii	Pink Flowering Sumac	F
Rosmarinus species	Rosemary (except dwarf/prostrate variety)	F
Salvia species (numerous)	Sage	F, I
Salsola australis	Russian Thistle	F, I
Senecio serpens	No common name	FR
Solanum Xantii	Purple Nightshade (toxic)	I, Toxic
Solanum Douglasii	Douglas Nightshade	Toxic
Silybum marianum	Milk Thistle	F, I
Tecoma capensis	Cape Honeysuckle	F
Thuja species	Arborvitae	F
Urtica urens	Burning Nettle	F
Vinca major	Periwnkle	I

*F = flammable, I = Invasive,

NOTES:

1. Plants on this list that are considered invasive are a partial list of commonly found plants. There are many other plants considered invasive that shall not be planted in a fuel modification zone and they can be found on The California Invasive Plant Council's Website www.cal-ipc.org/ip/inventory/index.php. Other plants not considered invasive at this time may be determined to be invasive after further study.
2. The absence of a particular plant, shrub, groundcover, or tree, from this list does not necessarily mean it is fire resistive.
3. Native, drought tolerant, plants are encouraged unless they are on this Prohibited Plant list or otherwise known as flammable or Invasive.
4. **: certain species of Ceonothus, Saltbush and Sumac need to be maintained free of dead materials, which builds up in the plant. Remove any poison oak (Sumac).

Rincon 2011 Tree Survey Information

Tree Identification #	Scientific Name	Common Name	DBH (Inches)	Canopy Height (Feet)	Canopy Diameter (Feet)	Overall Health	Health Assessment Code
1	Eucalyptus sp.	Eucalyptus	27	35	20	Average	C
2	Schinus molle	Pepper	10	12	10	Average	C
3	Schinus molle	Pepper	13	13	15	Average	C
4	Schinus molle	Pepper	13	20	15	Average	C
5	Eucalyptus sp.	Pepper	21	35	20	Average	C
6	Schinus molle	Pepper	14	25	20	Average	C
7	Eucalyptus sp.	Eucalyptus	30	15	0	Average	C
8	Schinus molle	Pepper	25	15	0	Average	C
9	Schinus molle	Pepper	16	25	15	Average	C
10	Eucalyptus sp.	Eucalyptus	13	50	15	Below Average	D
11	Eucalyptus sp.	Eucalyptus	30	15	0	Below Average	D
12	Eucalyptus sp.	Eucalyptus	22	60	20	Below Average	D
13	Eucalyptus sp.	Eucalyptus	16	20	10	Average	C
14	Eucalyptus sp.	Eucalyptus	19	40	20	Below Average	D
15	Eucalyptus sp.	Eucalyptus	18	35	15	Below Average	D
16	Eucalyptus sp.	Eucalyptus	17	30	10	Below Average	D
17	Eucalyptus sp.	Eucalyptus	17	30	10	Below Average	D
18	Eucalyptus sp.	Eucalyptus	38	35	15	Below Average	D
19	Eucalyptus sp.	Eucalyptus	12	30	15	Below Average	D
20	Eucalyptus sp.	Eucalyptus	33	30	15	Below Average	D
21	Eucalyptus sp.	Eucalyptus	34	35	20	Below Average	D
22	Eucalyptus sp.	Eucalyptus	10	30	15	Below Average	D
23	Eucalyptus sp.	Eucalyptus	22	25	10	Below Average	D
24	Eucalyptus sp.	Eucalyptus	31	35	15	Below Average	D
25	Eucalyptus sp.	Eucalyptus	15	20	10	Below Average	D
26	Eucalyptus sp.	Eucalyptus	22	25	15	Below Average	D
27	Eucalyptus sp.	Eucalyptus	35	15	0	Below Average	D
28	Eucalyptus sp.	Eucalyptus	17	25	10	Below Average	D
29	Eucalyptus sp.	Eucalyptus	21	20	10	Below Average	D
30	Eucalyptus sp.	Eucalyptus	15	20	10	Below Average	D
31	Eucalyptus sp.	Eucalyptus	25	25	15	Below Average	D
32	Eucalyptus sp.	Eucalyptus	28	30	15	Below Average	D
33	Eucalyptus sp.	Eucalyptus	23	15	10	Below Average	D
34	Eucalyptus sp.	Eucalyptus	32	25	10	Below Average	D
35	Eucalyptus sp.	Eucalyptus	24	45	20	Below Average	D
36	Eucalyptus sp.	Eucalyptus	36	45	20	Below Average	D
37	Eucalyptus sp.	Eucalyptus	12	20	10	Below Average	D
38	Eucalyptus sp.	Eucalyptus	16	25	15	Below Average	D
39	Eucalyptus sp.	Eucalyptus	24	20	15	Below Average	D
40	Eucalyptus sp.	Eucalyptus	27	40	15	Average	C

41	Eucalyptus sp.	Eucalyptus	13	20	15	Below Average	D

Subject: **Jurisdictional Delineation within the Hitch Ranch Specific Plan Project Site, City of Moorpark, Ventura County, California**

Dear Ms. Rapista:

This letter report has been prepared by Rincon Consultants, Inc. (Rincon) to assist Comstock Homes with project planning, and for use by the United States Army Corps of Engineers (USACE) to confirm extent of potential jurisdiction under Section 404 of the Clean Water Act, the Regional Water Quality Control Board (RWQCB), to confirm extent of potential jurisdiction pursuant to Section 401 of the Clean Water Act and the Porter-Cologne Water Quality Control Act, and the California Department of Fish and Wildlife (CDFW) jurisdiction pursuant to California Fish and Game Code (CFGC) Section 1600 *et seq*.

This Jurisdictional Delineation (JD) identified two drainages potentially subject to agency jurisdiction. The findings and conclusions presented in this report, including the location and extent of areas potentially subject to regulatory jurisdictions, represent the professional opinion of the consultant biologists. These findings and conclusions should be considered preliminary and at final discretion of the applicable resource agency.

Summary of Project Description

The proposed Hitch Ranch Specific Plan (project) is designed as a mixed-density community in southeastern Ventura County in the City of Moorpark, between the Simi Hills and Little Simi Valley (Attachment A, Figure 1). The project provides for the arrangement of various land uses on the 277.3-acre project site. Proposed land uses include several types/intensities of residential land uses, a neighborhood park site, and flood-control facilities. Other improvements include storm drains, water mains, sanitary sewer lines, electric lines, natural gas lines, and telephone and cable lines.

Methods

This study included a literature review and desktop evaluation of existing aerial imagery and published datasets, followed by a field delineation of potential jurisdictional waters. The area surveyed was consistent with the limits of the project site and defined herein as the “study area” (Attachment B, Figure 2). The study area is situated within the *Moorpark, California* USGS 7.5-minute topographic quadrangle, Township 3 North, Range 19 West, San Bernardino Baseline and Meridian. While the entirety of the project site was part of the study area, particular focus was given to erosional and drainage features identified in previous biological studies (Barringer Biological Services, 2019).

Rincon Senior Biologist Robin Murray conducted the field survey on December 30, 2019. Follow-up observations at the site were made by Rincon Natural Resources Director Greg Ainsworth on May 26, 2021. The JD has been prepared in accordance with USACE, RWQCB and CDFW procedures, as outlined below.

Literature Review

Prior to the field survey, Rincon reviewed available background information and published datasets to understand the environmental setting and context of the study area to aide in characterizing the nature and extent of jurisdictional waters potentially occurring on the subject site. These existing resources included aerial imagery depicting the study area (Google Earth 2019), the most recent *Moorpark, California* USGS 7.5-minute topographic quadrangle map (2015), and the Web Soil Survey (USDA NRCS 2019a). The *National Hydrography Dataset* (USGS 2019) and the *National Wetlands Inventory* (NWI) (United States Fish and Wildlife Service 2019) were reviewed to determine if any potential wetlands and/or other waters had been previously mapped on or in the vicinity of the proposed project site. The *State Soils Data Access (SDA) Hydric Soils List* (USDA NRCS 2019b) was also reviewed to determine if any soil map unit types mapped on or near the study area were classified as hydric. Rincon also reviewed precipitation records for the area to understand typical precipitation patterns and average annual precipitation totals.

Field Delineation

Ms. Murray surveyed the study area on foot for potential wetlands and non-wetland aquatic resources including streams that might exhibit an ordinary high water mark (OHWM) and that might constitute waters of the U.S. and/or State. During the field delineation, Ms. Murray noted general site characteristics and documented vegetation present on site. Current federal and state policies, methods and guidelines were used to identify and delineate potential jurisdictional areas and are described in detail below.

Non-Wetland Waters of the United States

The lateral limits of USACE jurisdiction (i.e., width) for non-wetland waters were determined by the presence of physical characteristics indicative of the OHWM. The OHWM was identified in accordance with the applicable Code of Federal Regulations (CFR) sections (33 CFR 328.3 and 33 CFR 328.4) and Regulatory Guidance Letter 05-05 (USACE 2005), as well as in reference to various relevant technical publications, including, but not limited to: *Review of Ordinary High Water Mark Indicators for Delineating Arid Streams in the Southwestern United States* (USACE 2004), *Distribution of Ordinary High Water Mark (OHWM) Indicators and Their Reliability in Identifying the Limits of "Waters of the United States" in Arid Southwestern Channels (*USACE 2006*),* and *A Field Guide to Identification of the Ordinary High Water Mark (OHWM) in the Arid West Region of the United States* (USACE 2008b). The regulations were also reviewed in the determination of non-jurisdictional features including ephemeral drainages, artificially irrigated areas and roadway ditches excavated in uplands.

Additionally, Rincon evaluated sources of water, potential connections and distances to Traditional Navigable Waters (TNWs), streams that are perennial or intermittent in nature and other factors that affect whether waters qualify as "waters of the U.S." under the current 2020 Navigable Water Protection Rule. A more detailed regulatory definition of USACE jurisdiction can be found in Attachment B.

Wetland Waters of the United States

Potential wetland features were evaluated for presence of wetland indicators; specifically, hydrophytic vegetation, hydric soils, and wetland hydrology, according to routine delineation procedures within the *Wetlands Delineation Manual* (USACE 1987) and *Regional Supplement to the Corps of Engineers Wetland Delineation Manual: Arid West Region* (USACE 2008a). The USACE *Arid West 2018 Regional Wetland Plant List* was used to determine the wetland status of the examined vegetation by the following indicator status categories: Upland (UPL), Facultative Upland (FACU), Facultative (FAC), Facultative Wetland (FACW), and Obligate Wetland (OBL) (Lichvar et al. 2018). Representative sample points were sited in aeras most likely to exhibit wetland characteristics, i.e., a prevalence of hydrophytic vegetation and suitable landform, and examined in the field for potential wetland indicators. Sample points were not conducted in areas with an obvious prevalence of upland vegetation or in areas where the landform would not support wetland features, i.e. concrete channels and sloped areas. A more detailed regulatory definition of USACE jurisdiction can be found in Attachment B.

Waters of the State

The limits of "waters of the State," as defined under the Porter-Cologne Water Quality Control Act, are any surface water or groundwater, including saline waters, within the boundaries of the state. In those areas where a OHWM was present, the OHWM was determined to represent the limits of waters of the State based on current interpretation of jurisdiction by the Los Angeles RWQCB. In those areas where an OHWM was not present, but surface water was present, i.e. roadside ditches that are hydrologically connected to tributaries and TNWs, the limits of waters of the State were determined to be bounded by the top of slope or top of "bank."

Potential State wetland features were evaluated pursuant to the State Water Resources Control Board's (SWRCB) *State Wetland Definition and Procedures for Discharges of Dredged or Fill Material to Waters of the State* (SWRCB 2019). Potential state wetlands were evaluated following the SWRCB's definition, which relies on the same three parameters as the USACE definition (hydrophytic vegetation, wetland hydrology, and hydric soils) but allows for naturally unvegetated areas meeting the other two parameters to be considered wetlands. A more detailed regulatory definition of RWQCB jurisdiction can be found in Attachment B.

CDFW Streambeds

The extent of potential streambeds, streambanks, lakes and riparian habitat subject to CDFW jurisdiction under Sections 1600 *et seq*. of the California Fish and Game Code was delineated by reviewing the topography and morphology of potentially jurisdictional features to determine the outer limit of riparian vegetation, where present, or the tops of banks for stream features. A more detailed regulatory definition of CDFW jurisdiction can be found in Attachment B.

Ventura County

Potential redline channels were evaluated, specifically those channels that Ventura County has determined to convey about 500 cubic feet per second or more in a 100-year runoff event. A list of redline channels that were adopted in 1994 by the Ventura County Watershed Protection District were reviewed (Ventura County 2019). For the purposes of this report, the jurisdictional limits of redline channels were determined to be coterminous with USACE jurisdiction since Ventura County does not have guidance on extent of jurisdiction. A more detailed regulatory definition of Ventura County Watershed Protection District jurisdiction can be found in Attachment B.

Data Collection and Processing

Data points representing the top of bank, OHWM, and other observation points were mapped using a Trimble R1 Global Positioning System (GPS) with sub-meter accuracy and were also plotted on aerial photographs. The data were subsequently transferred to Rincon's geographic information system (GIS) and used in combination with recent, high resolution aerial photographs and, topographic datasets to map the extent of streams in the study area. The delineation data were used to produce Figure 1 through Figure 4 (Attachment A). Representative Photographs of delineated features and surrounding conditions are presented in Attachment C.

Existing Setting

Topography

The study area is located within the southwest portion of Ventura County and within the South Coast subregion as defined in the Jepson ecoregion system, which extends from Point Conception to the west southward to Mexico, along the immediate coasts in Ventura County, but also extending inland to the San Gabriel and San Bernardino mountains farther east and south (Baldwin et al. 2012). Elevations within the study area range from approximately 475 to 675 feet above mean sea level. The topography of the study area is characterized by moderately steep hills and canyons covered in open vegetation.

Climate

The project site is located in southern Ventura County, which is characterized by warm, dry summers and wet winters. Average annual precipitation in this area is approximately 14.6 inches, with most of the annual precipitation occurring between the months of December and March.

Hydrology

General hydrology of the study area was evaluated through review of topographic maps, aerial photos, and the National Hydrography Dataset (USGS 2019). The study area is located in Hydrologic Unit Code 18070103. The Simi Hills, north of the study area, generally drain in a southerly direction by a network of drainages that then converge with Arroyo Las Posas south of the study area. Based on an examination of aerial imagery and observation during the site visit, the systems appear to be somewhat "flashy", which is typical for the region and for semi-arid region streams in sandy substrates. Steep hills within the region generate runoff during storm events that collects and flows through the drainages.

Soils

Based on the most recent NRCS soil survey for Ventura County, California (U.S. Department of Agriculture 2019), the study area is underlain by the following soil types: San Andreas sandy loam, 30 to 50 percent slopes (34.4 percent), Chesterton coarse sandy loam, 5 to 15 percent slopes, eroded (25.2 percent), Garretson loam, 2 to 9 percent slopes (13.4 percent), Soper gravelly loam, 30 to 50 percent slopes, eroded (12.9 percent), Metz loamy sand, 2 to 9 percent slopes (7.8 percent), Mocho loam, 0 to 2 percent slopes (5.5 percent), and Arnold sand, 9 to 50 percent slopes (0.9 percent). These soils alluvial and derived from sedimentary or conglomerate rock, and range from moderately well drained to somewhat excessively drained. None of these soils are considered hydric (USDA 2019). Figure 2 depicts the soil types found within the study area.

Vegetation

Habitat classification is based on the classification systems provided in *A Manual of California Vegetation, Second Edition* (Sawyer et al., 2009). Seven terrestrial vegetation communities or land cover types were identified within the study area by Impact Sciences in 2011. The site is predominately vegetated by annual brome grasslands, with scattered patches of California sagebrush-deerweed scrub (*Artemisia californica-Acmispon glaber* shrubland association), coyote brush scrub (*Baccharis pilularis* shrubland alliance), and non-native woodland.

Field Results and Discussion

Based upon the findings of Rincon's jurisdictional delineation, the intermittent storm drain channel Walnut Canyon Drain, one unnamed ephemeral drainage (Drainage 1), and one unnamed erosional feature (Erosional Feature 1) are present in the study area. Representative photographs are provided in Attachment C.

Walnut Canyon Drain

The Walnut Canyon Drain is a rectangular concrete-lined drainage channel that extends along the southern edge of the study area. It is classified by the National Wetland Inventory (NWI, USFWS 2020) as a R4SBCx drainage (riverine, intermittent streambed, seasonally flooded, excavated). Constructed in 1962 (Ventura Countywide Stormwater Quality Management Program 2021), the Walnut Canyon Drain is also considered a redline stream by the Ventura County Watershed Protection District. Stormwater and runoff flows from residential developments and a natural drainage enter Walnut Canyon Drain north of the study area. Within the study area, the drainage flows from east to west, paralleling Poindexter Avenue. West of the study area, the drain travels in a southwesterly direction, until it connects to Arroyo Las Posas approximately 2.5 miles southwest of the study area. Arroyo Las Posas converges with Calleguas Creek, which then flows south to Mugu Lagoon, and ultimately to the Pacific Ocean. Based on its position within the watershed, it appears likely that the feature was a natural drainage prior to its excavation and channelization.

The Walnut Canyon Drain contains a distinct OHWM, bed, and banks, which were defined by the break in slope. The OHWM and top of bank measure eight feet wide, with the top of bank measuring five feet above the concrete-lined bed of the channel. Water was present in the drain during the May 26, 2021 survey, suggesting the feature transmits flows on an intermittent basis. The water appeared to be fed by runoff from the upstream residential developments. Walnut Canyon Drain is likely subject to regulations by the USACE and RWQCB under Sections 404 and 401 of the CWA, respectively, as well as CDFW pursuant to Section 1600 *et seq*. of the CFGC (Attachment A, Figure 4).

Unnamed Drainage 1

Drainage 1 is an ephemeral drainage that experiences surface flow during the winter/wet season and during storm events. It is classified by the NWI as a R4SBC drainage (riverine, intermittent streambed, seasonally flooded). Within the northern portion of the drainage, a clearly incised channel with steeply defined bed and banks was observed. An OHWM was discernible within Drainage 1, and was mapped based on the presence of shelving, sediment and debris deposits, and matted vegetation indicating ordinary hydrologic flows associated with rain events. As the feature flows downstream into lower elevations and gradient, defined banks become less incised and recognizable, though transport of

sediment within the feature remained consistent throughout its length. Drainage 1 flows south and converges with the Walnut Canyon Drain.

The bed of the channel is largely unvegetated and consists of coarse sand. The banks of the channel are primarily vegetated by annual brome grassland, which is contiguous with the surrounding landscape in its vicinity. This community is dominated by non-native grasses and forbs, including ripgut brome (*Bromus diandrus*), soft chess (*Bromus hordeaceus*), red brome (*Bromus madritensis*), slender oat (*Avena barbata*), fennel (*Foeniculum vulgare*), Italian thistle (*Carduus pycnocephalus*), tocalote (*Centaurea melitensis*), black mustard (*Brassica nigra*), red stem filaree (*Erodium cicutarium*), horehound (*Marrubium vulgare*), and turkey mullein (*Croton setiger*). Within the northern portion of the drainage, it is vegetated by non-native woodland dominated by blue gum eucalyptus (*Eucalyptus globulus*), with an herbaceous layer of annual brome grassland. As the drainage flows south, it parallels a windrow of Peruvian pepper trees (*Schinus molle*), with an herbaceous layer of annual brome grassland.

Soft chess and horehound are ranked as FACU species, and red brome is ranked as an UPL species (Lichvar et al. 2016; USACE 2016). The remaining dominant plant species within the annual brome grassland observed along the banks of the drainage do not have a wetland indicator status. Based on the dominance of upland plant species throughout the drainage and the soils consisting of coarse sand, Drainage 1 is not considered a wetland.

Under the Navigable Water Protection Rule, ephemeral features are exempted from USACE jurisdiction; therefore, it is expected that Drainage 1 is subject to RWQCB and CDFW jurisdiction, but not USACE jurisdiction (Attachment A, Figure 5).

Erosional Feature 1 (Non-jurisdictional)

Erosional Feature 1 is situated within the northeast corner of the study area. The feature is not mapped by the NWI (USFWS 2020). It originates at the northern boundary of the property, near the southern terminus of Meridian Hills Drive, which is situated directly north of the property boundary. The feature originates at a culvert outfall, and travels in a southerly direction into the study area. The feature is very steeply incised in the north, but quickly becomes less defined as the surrounding topography becomes less steep and abates into the landscape after approximately 500 feet. No indicators of hydrophytic vegetation or hydric soils were evident. The erosional feature may briefly convey flow from upland areas during storm events over a short period of time, but it does not exhibit a defined bed, bank, channel, or OHWM indicative of a jurisdictional drainage feature. Review of historical aerial photographs confirms that the feature was not present prior to 2005, when Meridian Hills Drive was constructed. Therefore, this feature is not expected to be subject to USACE, RWQCB, and CDFW jurisdictions.

Summary of Jurisdictional Areas

Potentially jurisdictional areas within the study area are identified below in Table 1 and shown on Figures 4 and 5.

Table 1 USACE, RWQCB, and CDFW Jurisdictional Areas

Feature	Waters of the U.S.[1]		Waters of the State[2] (acres/linear feet)	CDFW Jurisdictional Streambed[2] (acres/linear feet)
	Non-wetland Waters of the U.S. (acres/linear feet)	Wetland Waters of the U.S. (acres/linear feet)		
Walnut Canyon Drain	1.02 acre/ 4,996 feet	--/ --	1.02 acre/ 4,996 feet	1.02 acre/ 4,996 feet

[2]Calculated to top of bank

Conclusions and Recommendations

The Walnut Canyon Drain is likely subject to regulation by the USACE and RWQCB under Sections 404 and 401 of the CWA, respectively, as well as CDFW pursuant to Section 1600 *et seq*. of the CFGC. Walnut Canyon Drain is also subject to Ventura County Watershed Protection District jurisdiction as a redline drainage. Drainage 1 is likely subject to regulation by the RWQCB under Section 401 of the CWA as well as CDFW pursuant to Section 1600 *et seq*. of the CFGC.

The findings and conclusions presented in this report, including the location and extent of areas subject to regulatory jurisdiction, represent the professional opinion of the consultant biologists. These findings and conclusions should be considered preliminary and at final discretion of the applicable resource agency.

Sincerely,
Rincon Consultants, Inc.

Attachment B Regulatory Framework

The following is a brief summary of the regulatory context under which biological resources are managed at the federal, State, and local levels. A number of federal and State statutes provide a regulatory structure which guide the protection of jurisdictional features. Agencies with the responsibility for protection of jurisdictional features within the project site include:

- United States Army Corps of Engineers (non-wetland waters and wetlands of the United States)
- Regional Water Quality Control Board (waters of the State)
- California Department Fish and Wildlife (riparian areas, streambeds, and lakes)
- California Coastal Commission (coastal wetlands)

United States Army Corps of Engineers Jurisdiction

The United States Army Corps of Engineers (USACE), is responsible for administering several federal programs related to ensuring the quality and navigability of the nation's waters.

Clean Water Act Section 404

Congress enacted the CWA "to restore and maintain the chemical, physical, and biological integrity of the Nation's waters." Under provisions of Section 404 of the Clean Water Act (CWA), the USACE regulates the placement of dredge or fill material into "waters of the United States." In administering this program, the USACE must consider factors including the need to minimize impacts while maintaining the applicant's objectives to the extent practicable, and the CWA's requirement that any permitted discharge of fill must be the least environmentally damaging practicable alternative. The process of obtaining a Section 404 permit can be onerous, and may include public noticing and comment, a robust alternatives analysis performed under the U.S. Environmental Protection Agency's (USEPA) Clean Water Act Section 404(b)(1) Guidelines, environmental review under the National Environmental Policy Act, required interagency consultation processes triggered by other federal laws, and costly compensatory mitigation.

To streamline the permitting process for routine types of projects the USACE has determined will have only minimal environmental impacts, the USACE has issued a series of General Permits, including Nationwide Permits (NWPs) issued at the national level and Regional General Permits (RGPs) issued at the regional level. For activities that meet the criteria, qualifying for coverage under a General Permit can be a boon because it eliminates the most complex steps in the permitting process (404(b)(1) analysis and NEPA review).

Waters of the U.S.

On April 21, 2020, the USACE and U.S. Environmental Protection Agency published the *Navigable Waters Protection Rule to define "Waters of the United States."* This rule, effective on June 22, 2020, defines four categories of jurisdictional features, documents certain types of waters that are excluded from

jurisdiction, and clarifies some regulatory terms. Under the *Navigable Waters Protection Rule*, "waters of the United States" include:

Territorial seas and traditional navigable waters;

Perennial and intermittent tributaries that contribute surface flow to those waters;

Certain Lakes and ponds, and impoundments of jurisdictional waters, and;

Wetlands adjacent to jurisdictional waters.

Tributaries are defined as "a river, stream, or similar naturally occurring surface water channel that contributes surface water flow to the territorial seas or traditional navigable waters in a typical year either directly or through one or more tributaries, jurisdictional lakes, ponds, and impoundments of jurisdictional waters, or adjacent wetlands." The tributary category also includes a ditch that "either relocates a tributary, is constructed in a tributary, or is constructed in an adjacent wetland as long as the ditch is perennial or intermittent and contributes surface water flow to a traditional navigable water or territorial sea in a typical year."

Adjacent wetlands are defined as wetlands that:

(i) Abut, meaning to touch at least at one point or side of, a defined water of the U.S.;

(ii) Are inundated by flooding from a defined water of the U.S in a typical year;

(iii) Are physically separated from a defined water of the U.S. by a natural berm, bank, dune, or similar natural features or by artificial dike, barrier or similar artificial structures as long as direct hydrological surface connection to defined Waters of the U.S. are allowed; or,

(iv) Are physically separated from a defined water of the U.S. only by an artificial dike, barrier, or similar artificial structure so long as that structure allows for a direct hydrologic surface connection between the wetlands and the defined water of the U.S. in a typical year, such as through a culvert, flood or tide gate, pump, or similar artificial feature. An adjacent wetland is jurisdictional in its entirety when a road or similar artificial structure divides the wetland, as long as the structure allows for a direct hydrologic surface connection through or over that structure in a typical year.

The Navigable Waters Protection Rule states that the following areas not considered to be jurisdictional features even where they otherwise meet the definitions described above:

1) Groundwater, including groundwater drained through subsurface drainage systems;
2) Ephemeral features that flow only in direct response to precipitation including ephemeral streams, swales, gullies, rills and pools;
3) Diffuse stormwater runoff and directional sheet flow over uplands;
4) Ditches that are not defined Waters of the U.S. and not constructed in adjacent wetlands subject to certain limitations;
5) Prior converted cropland;
6) Artificially irrigated areas that would revert to upland if artificial irrigation ceases;
7) Artificial lakes and ponds that are not jurisdictional impoundments and that are constructed or excavated in upland or non-jurisdictional waters;
8) Water-filled depressions constructed or excavated in upland or in non-jurisdictional waters for the purpose of obtaining fill, sand, or gravel;
9) Stormwater control features constructed or excavated in uplands or in non-jurisdictional water to convey, treat, infiltrate, or stormwater run-off;

10) Groundwater recharge, water reuse, and wastewater recycling structures constructed or excavated in upland or in non-jurisdictional waters; and,
11) Waste treatment systems.

USACE jurisdictional limits are typically identified by the ordinary high water mark (OHWM) or the landward edge of adjacent wetlands (where present). The OHWM is the "line on the shore established by the fluctuations of water and indicated by physical characteristics such as a clear, natural line impressed on the bank, shelving, changes in the character of soil, destruction of terrestrial vegetation, the presence of litter and debris, or other appropriate means that consider the characteristics of the surrounding area" (33 CFR 328.3).

Wetlands

The USACE defines wetlands as "those areas that are inundated or saturated by surface or groundwater at a frequency and duration sufficient to support, and that under normal circumstances do support, a prevalence of vegetation typically adapted for life in saturated soil conditions" (33 CFR 328.3). The USACE's delineation procedures identify wetlands in the field based on indicators of three wetland parameters: hydrophytic vegetation, hydric soils, and wetland hydrology. The following is a discussion of each of these parameters.

Hydrophytic Vegetation

Hydrophytic vegetation dominates areas where frequency and duration of inundation or soil saturation exerts a controlling influence on the plant species present. Plant species are assigned wetland indicator status according to the probability of their occurring in wetlands. More than fifty percent of the dominant plant species must have a wetland indicator status to meet the hydrophytic vegetation criterion. The USACE published the National Wetland Plant List (USACE 2018), which separates vascular plants into the following four basic categories based on plant species frequency of occurrence in wetlands:

Obligate Wetland (OBL). Almost always occur in wetlands

Facultative Wetland (FACW). Usually occur in wetlands, but occasionally found in non-wetlands

Facultative (FAC). Occur in wetlands or non-wetlands

Facultative Upland (FACU). Usually occur in non-wetlands, but may occur in wetlands

Obligate Upland (UPL). Almost never occur in wetlands

The USACE considers OBL, FACW and FAC species to be indicators of wetlands. An area is considered to have hydrophytic vegetation when greater than 50 percent of the dominant species in each vegetative stratum (tree, shrub, and herb) fall within these categories. Any species not appearing on the United States Fish and Wildlife Service's list is assumed to be an upland species, almost never occurring in wetlands. In addition, an area needs to contain at least 5% vegetative cover to be considered as a vegetated wetland.

Hydric Soils

Hydric soils are saturated or inundated for a sufficient duration during the growing season to develop anaerobic or reducing conditions that favor the growth and regeneration of hydrophytic vegetation. Field indicators of wetland soils include observations of ponding, inundation, saturation, dark (low

chroma) soil colors, bright mottles (concentrations of oxidized minerals such as iron), gleying (indicates reducing conditions by a blue-grey color), or accumulation of organic material. Additional supporting information includes documentation of soil as hydric or reference to wet conditions in the local soils survey, both of which must be verified in the field.

Wetland Hydrology

Wetland hydrology is inundation or soil saturation with a frequency and duration long enough to cause the development of hydric soils and plant communities dominated by hydrophytic vegetation. If direct observation of wetland hydrology is not possible (as in seasonal wetlands), or records of wetland hydrology are not available (such as stream gauges), assessment of wetland hydrology is frequently supported by field indicators, such as water marks, drift lines, sediment deposits, or drainage patterns in wetlands.

Rivers and Harbors Act Section 10

Section 10 of the Rivers and Harbors Act of 1899 requires authorization from the USACE for the construction of any structure in or over any navigable water of the United States. Structures or work outside the limits defined for navigable waters of the United States require a Section 10 permit if the structure or work affects the course, location, or condition of the water body. The law applies to any dredging or disposal of dredged materials, excavation, filling, re-channelization, or any other modification of a navigable water of the United States, and applies to all structures and work. It further includes, without limitation, any wharf, dolphin, weir, boom breakwater, jetty, groin, bank protection (e.g. riprap, revetment, bulkhead), mooring structures such as pilings, aerial or subaqueous power transmission lines, intake or outfall pipes, permanently moored floating vessel, tunnel, artificial canal, boat ramp, aids to navigation, and any other permanent, or semi-permanent obstacle or obstruction. It is important to note that Section 10 applies only to navigable waters, and thus does not apply to work in non-navigable wetlands or tributaries. In some cases, Section 10 authorization is issued by the USACE concurrently with CWA Section 404 authorization, such as when certain Nationwide Permits are used.

Regional Water Quality Control Board Jurisdiction

The State Water Resources Control Board (SWRCB) and nine Regional Water Quality Control Boards (RWQCBs) have jurisdiction over “waters of the State,” which are defined as any surface water or groundwater, including saline waters, within the boundaries of the state (California Water Code sec. 13050(e)). These agencies also have responsibilities for administering portions of the CWA.

Clean Water Act Section 401

Section 401 of the CWA requires an applicant requesting a federal license or permit for an activity that may result in any discharge into navigable waters (such as a Section 404 Permit) to provide state certification that the proposed activity will not violate state and federal water quality standards. In California, CWA Section 401 Water Quality Certification (Section 401 Certification) is issued by the RWQCBs and by the SWRCB for multi-region projects. The process begins when an applicant requests a pre-application meeting with the RWQCB, waits no less than 30 days, and then submits an application to the RWQCB and informs the USACE (or the applicable agency from which a license or permit was requested) that an application has been submitted. The USACE will then determine a “reasonable period

of time" for the RWQCB to act on the application; this is typically 60 days for routine projects and longer for complex projects but may not exceed one year. Under current regulations, once initiated, the reasonable period of time cannot be stopped or paused. When the period has elapsed, if the RWQCB has not either issued or denied the application for Section 401 Certification, the USACE may determine that Certification has been waived and issue the requested permit. If a Section 401 Certification is issued it may include binding conditions, imposed either through the Certification itself or through the requested federal license or permit.

Porter-Cologne Water Quality Control Act

The Porter-Cologne Water Quality Control Act (Porter-Cologne Act) is the principal law governing water quality regulation in California. It establishes a comprehensive program to protect water quality and the beneficial uses of water. The Porter-Cologne Act applies to surface waters, wetlands, and ground water and to both point and nonpoint sources of pollution. Pursuant to the Porter-Cologne Act (California Water Code section 13000 *et seq*.), the policy of the State is as follows:

- The quality of all the waters of the State shall be protected
- All activities and factors affecting the quality of water shall be regulated to attain the highest water quality within reason
- The State must be prepared to exercise its full power and jurisdiction to protect the quality of water in the State from degradation

The Porter-Cologne Act established nine RWQCBs (based on watershed boundaries) and the SWRCB, which are charged with implementing its provisions and which have primary responsibility for protecting water quality in California. The SWRCB provides program guidance and oversight, allocates funds, and reviews RWQCB decisions. In addition, the SWRCB allocates rights to the use of surface water. The RWQCBs have primary responsibility for individual permitting, inspection, and enforcement actions within each of nine hydrologic regions. The SWRCB and RWQCBs have numerous nonpoint source related responsibilities, including monitoring and assessment, planning, financial assistance, and management.

Section 13260 of the Porter-Cologne Act requires any person discharging or proposing to discharge waste that could affect the quality of waters of the State to file a Report of Waste Discharge with the appropriate RWQCB. The RWQCB may then authorize the discharge, subject to conditions, by issuing Waste Discharge Requirements (WDRs). While this requirement was historically applied primarily to outfalls and similar point source discharges, the SWRCB's *State Wetland Definition and Procedures for Discharges of Dredged or Fill Material to Waters of the State*, effective May 2020, make it clear that the agency will apply the Porter-Cologne Act's requirements to discharges of dredge and fill material as well. The *Procedures* state that they are to be used in issuing CWA Section 401 Certifications and WDRs, and largely mirror the existing review requirements for CWA Section 404 Permits and Section 401 Certifications, incorporating most elements of the USEPA's *Section 404(b)(1) Guidelines*. Following issuance of the *Procedures*, the SWRCB produced a consolidated application form for dredge/fill discharges that can be used to obtain a CWA Section 401 Water Quality Certification, WDRs, or both.

Non-Wetland Waters of the State

The SWRCB and RWQCBs have not established regulations for field determinations of waters of the state except for wetlands currently. In many cases the RWQCBs interpret the limits of waters of the State to

be bounded by the OHWM unless isolated conditions or ephemeral waters are present. However, in the absence of statewide guidance each RWQCB may interpret jurisdictional boundaries within their region and the SWRCB has encouraged applicants to confirm jurisdictional limits with their RWQCB before submitting applications. As determined by the RWQCB, waters of the State may include riparian areas or other locations outside the OHWM, leading to a larger jurisdictional area over a given water body compared to the USACE.

Wetland Waters of the State

Procedures for defining wetland waters of the State pursuant to the SWRCB's *State Wetland Definition and Procedures for Discharges of Dredged or Fill Material to Waters of the State* went into effect May 28, 2020. The SWRCB defines an area as wetland if, under normal circumstances:

1) the area has continuous or recurrent saturation of the upper substrate caused by groundwater, or shallow surface water, or both;
2) the duration of such saturation is sufficient to cause anaerobic conditions in the upper substrate; and
3) the area's vegetation is dominated by hydrophytes or the area lacks vegetation.

The SWRCB's *Implementation Guidance for the Wetland Definition and Procedures for Discharges of Dredge and Fill Material to Waters of the State* (2020), states that waters of the U.S. and waters of the State should be delineated using the standard USACE delineation procedures, taking into consideration that the methods shall be modified only to allow for the fact that a lack of vegetation does not preclude an area from meeting the definition of a wetland.

California Department of Fish and Wildlife Jurisdiction

California Fish and Game Code section 1602 states that it is unlawful for any person to "substantially divert or obstruct the natural flow of, or substantially change or use any material from the bed, channel, or bank of, any river, stream, or lake" without first notifying the California Department of Fish and Wildlife (CDFW) of that activity. Thereafter, if CDFW determines and informs the entity that the activity will not substantially adversely affect any existing fish or wildlife resources, the entity may commence the activity. If, however, CDFG determines that the activity may substantially adversely affect an existing fish or wildlife resource, the entity may be required to obtain from CDFW a Streambed Alteration Agreement (SAA), which will include reasonable measures necessary to protect the affected resource(s), before the entity may conduct the activity described in the notification. Upon receiving a complete Notification of Lake/Streambed Alteration, CDFW has 60 days to present the entity with a Draft SAA. Upon review of the Draft SAA by the applicant, any problematic terms are negotiated with CDFW and a final SAA is executed.

The CDFW has not defined the term "stream" for the purposes of implementing its regulatory program under Section 1602, and the agency has not promulgated regulations directing how jurisdictional streambeds may be identified, or how their limits should be delineated. However, four relevant sources of information offer insight as to the appropriate limits of CDFW jurisdiction as discussed below.

- **The plain language of Section 1602 of CFGC** establishes the following general concepts:
  - References "river," "stream," and "lake"
  - References "natural flow"

- References "bed," "bank," and "channel"

- **Applicable court decisions**, in particular *Rutherford v. State of California* (188 Cal App. 3d 1276 (1987), which interpreted Section 1602's use of "stream" to be as defined in common law. The Court indicated that a "stream" is commonly understood to:
  - Have a source and a terminus
  - Have banks and a channel
  - Convey flow at least periodically, but need not flow continuously and may at times appear outwardly dry
  - Represent the depression between the banks worn by the regular and usual flow of the water
  - Include the area between the opposing banks measured from the foot of the banks from the top of the water at its ordinary stage, including intervening sand bars
  - Include the land that is covered by the water in its ordinary low stage
  - Include lands below the OHWM

- **CDFW regulations** defining "stream" for other purposes, including sport fishing (14 CCR 1.72) and streambed alterations associated with cannabis production (14 CCR 722(c)(21)), which indicate that a stream:
  - Flows at least periodically or intermittently
  - Flows through a bed or channel having banks
  - Supports fish or aquatic life
  - Can be dry for a period of time
  - Includes watercourses where surface or subsurface flow supports or has supported riparian vegetation

- **Guidance documents**, *including A Field Guide to Lake and Streambed Alteration Agreements* (CDFG 1994) and *Methods to Describe and Delineate Episodic Stream Processes on Arid Landscapes for Permitting Utility-Scale Solar Power Plants* (Brady and Vyverberg 2013), which suggest the following:
  - A stream may flow perennially or episodically
  - A stream is defined by the course in which water currently flows, or has flowed during the historic hydrologic course regime (approximately the last 200 years)
  - Width of a stream course can reasonably be identified by physical or biological indicators
  - A stream may have one or more channels (single thread vs. compound form)
  - Features such as braided channels, low-flow channels, active channels, banks associated with secondary channels, floodplains, islands, and stream-associated vegetation, are interconnected parts of the watercourse
  - Canals, aqueducts, irrigation ditches, and other means of water conveyance can be considered streams if they support aquatic life, riparian vegetation, or stream-dependent terrestrial wildlife
  - Biologic components of a stream may include aquatic and riparian vegetation, all aquatic animals including fish, amphibians, reptiles, invertebrates, and terrestrial species which derive benefits from the stream system
  - The lateral extent of a stream can be measured in different ways depending on the particular situation and the type of fish or wildlife resource at risk

The tenets listed above, among others, are applied to establish the boundaries of streambeds in various environments. Importance of each factor may be weighted based on site-specific considerations and the applicability of the indicators to the streambed at hand.

Ventura County Jurisdiction

Ventura County Watershed Protection District, which implements the Flood Plain Management Ordinance 3841 on behalf of Ventura County ensures compliance with the National Flood Insurance Program. This includes review of structures built in the floodplain affecting the bed, banks and overflow areas of District jurisdictional redline channels. The list of redline channels was adopted by the District Board of Supervisors in 1960, and then updated and confirmed by them in 1994. Ventura County defines a redline channel as follows:

- Most of the redline channels convey about 500 cubic feet per second or more in a 100-year runoff event.

2019 Geotechnical Feasibility Investigation

ALBUS-KEEFE & ASSOCIATES, INC
GEOTECHNICAL CONSULTANTS

September 20, 2019
J.N.: 2677.00

Ms. Harriet Rapista
Comstock Homes
2301 Rosecrans Avenue, Ste. 1150
El Segundo, CA 90245

Subject: **"Updated" Geotechnical Feasibility Investigation for Proposed Residential Development, Tentative Tract 5708 (Hitch Ranch Project), City of Moorpark, California.**

Dear Ms. Rapista,

Albus-Keefe & Associates, Inc. is pleased to present to you our "updated" geotechnical feasibility investigation for the subject site. This report was updated from our previous report, dated May 31, 2019, based on the most current tentative tract map for the site, dated September 20, 2019. This report presents a summary of our review of geologic literature for the site and vicinity, subsurface exploration, laboratory testing and engineering analyses. Conclusions relevant to the feasibility of the proposed development as well as preliminary recommendations for design and construction of the development are also presented herein based on the findings of our work.

While this report is comprehensive for feasibility evaluation purposes, it is not intended for final design purposes. As such, additional geotechnical studies may be warranted based on our review of future rough grading plans and foundation plans.

We appreciate this opportunity to be of service to you. If you should have any questions regarding the contents of this report, please do not hesitate to call our office.

Sincerely yours,

ALBUS-KEEFE & ASSOCIATES, INC.

David E. Albus
Principal Engineer

1.0 INTRODUCTION

1.1 PURPOSE AND SCOPE

The purpose of our work was to evaluate the feasibility of proposed site development. The scope of our work for this investigation was focused primarily on the geotechnical issues that could have significant impacts on future site development. The scope of our work for this investigation included the following:

- Review of published geologic and seismic data for the site vicinity
- Review of historical aerial photographs for the site vicinity
- Review of previous geotechnical reports for the site by Gorian and Associates, Inc. (Gorian)
- Review of previous geotechnical reports prepared by others in the surrounding area
- Review of our previous fault report for the site
- Review of the referenced preliminary grading, drainage, and utilities plans
- Geologic field mapping
- Exploratory drilling, trenching and sampling
- Laboratory testing of selected soil samples
- Engineering analyses of data obtained from our exploration and laboratory testing
- Evaluation of site seismicity, liquefaction, settlement potential, and slope stability
- Preparation of this report

1.2 SITE LOCATION AND DESCRIPTION

The site is a 277-acre, irregular-shaped parcel located north of Poindexter Avenue and approximately 1,500 feet west of Moorpark Avenue in the city of Moorpark, California. The site is generally bordered by undeveloped hillside property on the north, a new single-family housing tract on the northeast, rural single-family residences and Walnut Canyon Elementary School on the east, undeveloped hillside property on the west, rural single-family residences on the northwest, and by Southern Pacific Railroad tracks, Walnut Canyon Channel, and Poindexter Avenue on the south. The location of the site and its relationship to the surrounding area is shown on Figure 1, Site Location Map.

© 2019 Google

N

SITE LOCATION MAP

Proposed Residential Development
Tentative Tract Map No. 5708
(Hitch Ranch Project)
Moorpark, California

NOT TO SCALE

FIGURE 1

Topographically, the site consists of gentle- to steep-sloping hills dissected by south to southwest draining canyons. The southern margin of the site also represents the geomorphic transition from the hillside area of Moorpark to the valley area. Surface elevations within the site vary from 470 feet above mean sea level (MSL) within the southern, valley portion of the site to as much as 722 feet above MSL on the hilltops within the northern portion of the site. The gradients of natural slopes within the property range from nearly flat to 1.5:1 (H:V). Several manufactured slopes are also present throughout the site and range from 3:1 (H:V) to locally as steep as 1.5:1 (H:V).

Surface runoff within the site is generally by rill and sheet flow from the hillsides into the south and southwest draining swales and valleys. Offsite surface runoff is also directed onto the site via multiple through-going valleys from neighboring properties to the north. Drainage is cut off at the south property line by the west-flowing, concrete-lined Walnut Canyon Channel.

Vegetation within the site consists of a light to moderate growth of native grasses, weeds, and bushes. Scattered trees ranging in size from small to large are also present throughout the site.

1.3 PREVIOUS AND EXISTING LAND USE AND SITE IMPROVEMENTS

Based on our review of the previous geotechnical reports for the site by Gorian and historical aerial photographs from the 1930's through the early 1970's, the site was used for agricultural and ranching purposes. Only minor ranching operations from that time frame persist today while agricultural activities have been discontinued.

Existing site improvements observed on the property include a horse-stable, several small sheds, cattle pens, a medium-size water reservoir tank, and several small water tanks and troughs within the valley areas of the site. In addition, a paved street (Gabbert Road) and several high-voltage overhead power lines run north-south across the southwestern portion of the site. The perimeter of the site is also largely bounded by wire or chain-link fencing.

Remnants of former improvements associated with the former agricultural and earlier ranching operations are also scattered throughout the property. These remnants consist largely of concrete foundations on some of the hilltops within the central portion of the site, various irrigation pipelines, an abandoned above-ground steel tank in the northeastern portion of the site, and breached impoundment dams in some of the drainage areas.

Various ground modifications have been made to the property in association with the sites previous use. These modifications include terracing of select hillsides, flattening of the large drainage valleys through minor cut and fill grading, and construction of multiple dirt roads to access the majority of the site. The most significant ground modifications are present in the northwesterly portion of the site.

Based on recent discussions with the County of Ventura Watershed Protection District Groundwater Section, at least 15 water wells have also been drilled throughout the site (Dorrington, J., 2019). The approximate locations of known water wells are shown on the enclosed Geotechnical Map, Plates 1 & 2. The current status of most of these wells is unknown (e.g. active, abandoned, destroyed), but at least 3 are believed to be intact.

1.4 PROPOSED DEVELOPMENT

Based on our review of the Tentative Tract Map No. 5708, prepared by Encompass Consultant Group, dated September 20, 2019, the proposed site development will consist of six planning areas designated as single-family residential, multi-family residential and open space. Associated improvements will include public and private streets, and large detention basins located within the southern portion of the site. Some smaller detention basins are also proposed along the northerly margin of the development. The plan indicates that a main transecting street, identified as North Hills Parkway, will extend from the northeast corner of the site to Gabbert Road. The existing nearby streets Casey Road, High Street, and Meridian Hills Drive are also planned to be extended within the property and connect to proposed interior streets. Improvements are also proposed for Gabbert Road.

Rough grading of the site will consist of cuts and fills up to approximately 53 and 51 feet respectively, from the current grades. Cut and fill slopes are proposed at a maximum slope gradient of 2:1 (H:V) and maximum heights of approximately 75 feet and 61 feet, respectively. Fill-over cut slope at slope gradients of 2:1 (H:V) and 3:1 (H:V) are also proposed. The maximum height of a 2:1 (H:V) fill-over-cut slope is 80 feet. The maximum height of a 3:1 (H:V) fill-over-cut slope is 89 feet.

Details of the residential structures are not available at this time. We anticipate that future residential structures will consist of slab-on-grade, one- to three-story, wood-framed structures yielding relatively light structural loads. Other associated site improvements are anticipated to include utility services, asphalt and concrete pavements, decorative hardscape, and masonry retaining and screen walls.

With respects to onsite stormwater infiltration, discussions with the project civil engineer indicate that onsite stormwater infiltration is not proposed for the project.

2.0 INVESTIGATION

2.1 RESEARCH

2.1.1 Aerial Photographs and Geologic Publications and Maps

We reviewed aerial photographs, geologic publications and maps, and various other published geologic and groundwater studies for the site vicinity (see references). Data from these sources were utilized to develop our understanding of the general geologic conditions of the site.

2.1.2 Previous Geotechnical Investigations by Others

We reviewed previous geotechnical studies for the site, including responses, that were prepared by Gorian and Associates, Inc. (Gorian) between 1994 to 2009. See references for a complete listing of the studies that were available for our review. Their studies generally involved the excavation and logging of numerous exploration trenches and borings as well as the excavation and logging of long fault trenches to assess faulting in the southerly portion of site. These studies were utilized in developing some of the findings and conclusions presented herein. Pertinent exploratory and laboratory data presented by Gorian and Associates, Inc. are appended to this report (Appendix C). The locations of Gorian exploratory work, including fault trenches, are indicated on the enclosed Geotechnical Map, Plates 1 & 2.

We also reviewed previous geotechnical reports completed by various geotechnical consulting firms for neighboring properties. A listing of the reports we reviewed are summarized in the references.

2.1.3 Previous Fault Study by Albus-Keefe & Associates, Inc

We reviewed our fault study that was recently completed for the site under separate cover. The fault study was performed in order to evaluate the potential for future ground surface fault rupture within the project boundaries. Although the site is not located within the boundaries of an Earthquake Fault Zone (EFZ), the site is located in a seismically active area and fault studies by others in the city of Moorpark have reported active deformation (folding and faulting) outside the limits of EFZ's. Our field study was performed from January 21, 2019 through February 13, 2019 and involved the excavation and logging of two over-lapping exploratory trenches (FT-1 and FT-2) within the northeasterly margin of the site. The exploratory trenches were excavated utilizing a track-mounted excavator and had a combined length of 1540 linear feet and varied in depth from about 6 feet to up to 14 feet below the current ground surface. A summary of our findings, conclusions and recommendations relevant to our geologic assessment of surface fault rupture potential within the subject property is presented in our referenced report dated April 3, 2019. The report was later revised on June 3, 2019 in response to comments and recommendations by Mr. Jim O'Tousa (2019b), the geologic reviewer for RJR Engineering Group, representing the city of Moorpark. Our study was ultimately approved by Mr. Jim O'Tousa (2019a). Exploratory logs of our fault trenches are appended to this report (Appendix A-2). The locations of the fault trenches are indicated on the enclosed Geotechnical Map, Plates 1 & 2.

2.2 GEOLOGIC MAPPING

Geologic surface mapping of the site was performed in conjunction with our subsurface exploration in September and early October 2018. The surficial distributions of geologic conditions interpreted by this firm are presented on the enclosed Geotechnical Map, Plates 1 &2.

2.3 SUBSURFACE EXPLORATION

Subsurface exploration for this investigation was conducted in September and early October 2018 and consisted of excavating eleven (11) small-diameter borings, forty-six (46) exploratory trenches, and three (3) large-diameter borings throughout the site. The small-diameter borings and exploratory trenches were utilized to assist in evaluating the distribution and engineering characteristics of earth materials at the site. The small-diameter borings were excavated utilizing a truck-mounted, hollow-stem-auger drill rig to depths ranging from about 21.5 to 46.5 feet below the ground surface. The exploratory trenches were excavated utilizing a rubber-tired backhoe to depths ranging from about 5 feet to 14 feet below the ground surface. The large-diameter borings were utilized to evaluate slope stability in areas of proposed cut slopes. The large-diameter borings were drilled utilizing a truck-mounted, bucket-auger drill rig to depths ranging from about 44 to 80 feet below the ground surface.

Representatives of *Albus-Keefe & Associates, Inc*. logged the exploratory excavations. Visual and tactile identifications were made of the materials encountered, and their descriptions are presented on the exploration logs in Appendix A. The approximate locations of the exploratory excavations completed by this firm are shown on the enclosed Geotechnical Map, Plates 1 & 2.

Bulk, relatively undisturbed, and Standard Penetration Test (SPT) samples were obtained at selected depths within the exploratory borings for subsequent laboratory testing. Relatively undisturbed samples were obtained using a 3-inch O.D., 2.5-inch I.D., California split-spoon soil sampler lined with brass rings. SPT samples were obtained from the borings using a standard, unlined SPT soil sampler. For small-diameter borings, the sampler was driven 18 inches with successive drops of a 140-pound automatic hammer falling 30 inches. For the large-diameter borings, the sampler was driven 12 inches with successive drops of a Kelly bar. The number of blows required to advance the sampler was recorded for each six inches of advancement. The total blow count for the lower 12 inches of advancement per soil sample is recorded on the exploration logs. Samples were placed in sealed containers or plastic bags and transported to our laboratory for analyses.

Upon completion of drilling and sampling, the borings were backfilled with cuttings up to an elevation approximately matching the adjacent ground surface. While backfilling, the large-diameter borings were occasionally tamped with the Kelly bar. The exploratory trenches were backfilled with trench spoil to an elevation approximately matching the adjacent ground surface and wheel rolled at the ground surface.

2.4 LABORATORY TESTING

Selected soil samples obtained from our exploratory excavations were tested in our soil laboratory. Tests consisted of USCS classification, in-place moisture-density, maximum dry density/optimum moisture content, direct shear, consolidation/collapse potential, expansion index, soluble sulfate content, percent passing the No. 200 sieve, and Atterberg limits. All testing will be completed in accordance with current ASTM or acceptable industry standards. A description of laboratory test criteria and a summary of the test results are presented in Appendix B.

3.0 SUBSURFACE CONDITIONS

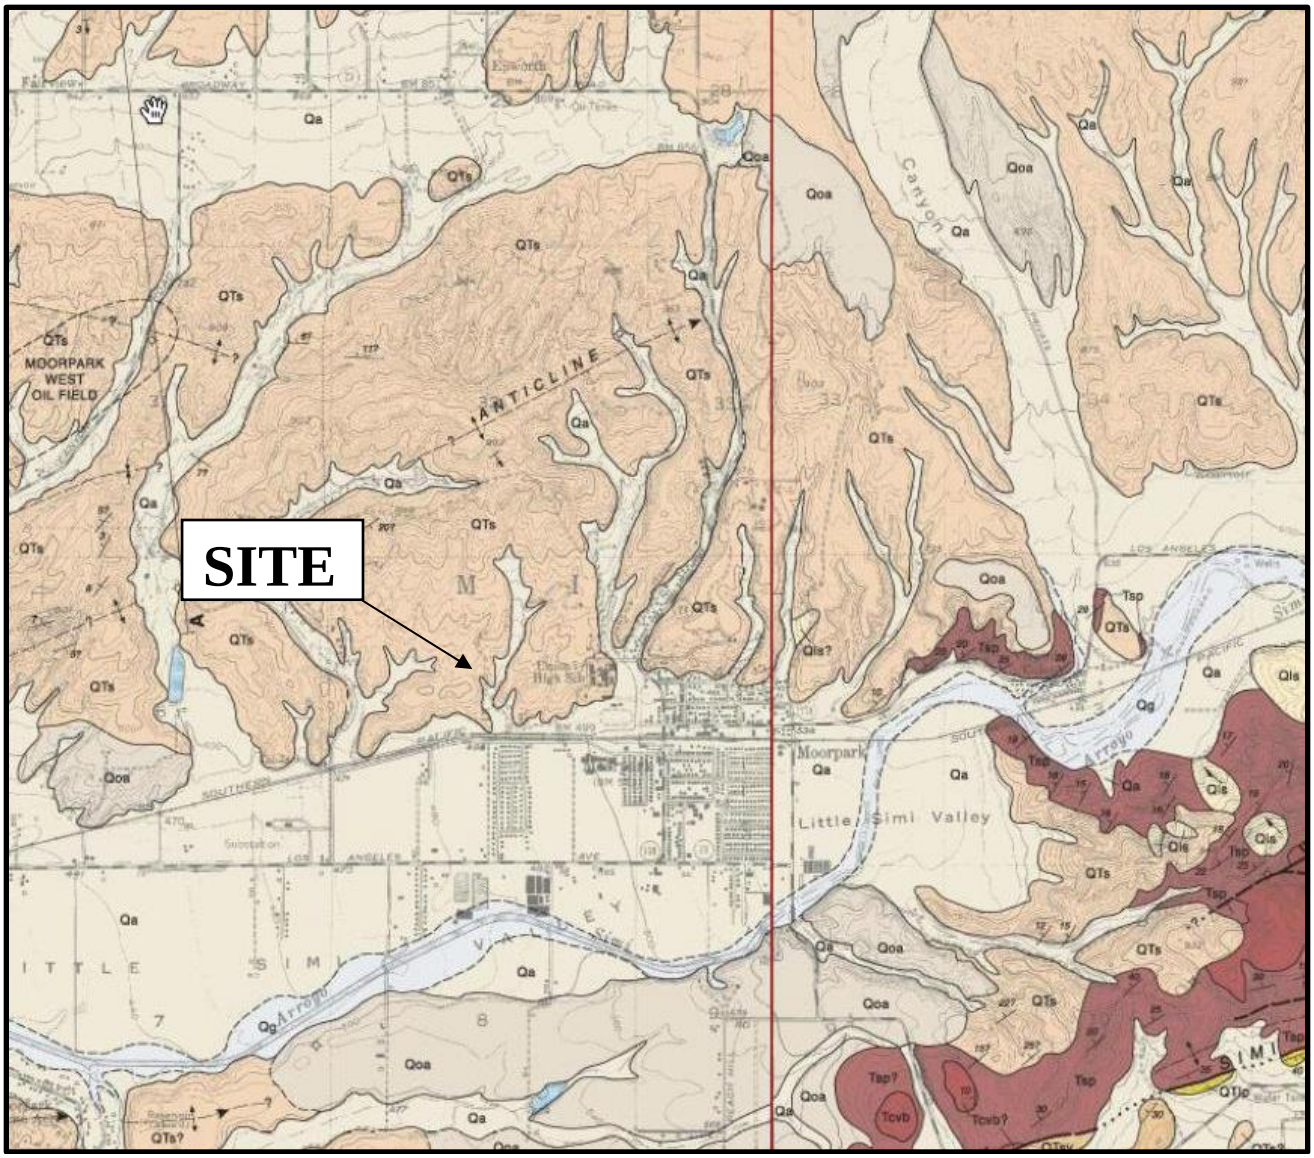
3.1 GEOLOGIC SETTING

The site is located within the south-central portion of the Ventura Basin in the western Transverse Ranges geomorphic province. The Ventura Basin is an east-west trending trough that experienced basin inversion (extensional to compressional forces) during late Miocene- to early Pliocene (Yeats, Huftile, & Stitt, 1994). The change from an extensional to compressional environment is believed to be associated with the development of the "Big Bend" of the San Andreas Fault to the north resulting in north-south crustal shortening of the region (DeVecchio et al., 2012b). Continued north-south compressional tectonics has produced an intricate system of east-west trending thrust faults, reverse faults, and large-scale folding throughout the basin.

In closer proximity, the site is located on the southern piedmont slopes of the Oak Ridge Mountains. The south margin of the site represents the geomorphic transitions to the valley floor (Little Simi Valley). The Oak Ridge Mountains have been tectonically uplifted in response to folding and reverse slip on the south-dipping Oak Ridge Fault. Across Little Simi Valley to the south, the north-dipping Simi-Santa Rosa fault system resulted in the uplift of the Las Posas Hills. Both faults underlie the Site at depth and result in crustal shortening of the vicinity. Deformation associated with the compression

between the Oak Ridge and Simi-Santa Rosa fault systems has resulted in a complex regime of folding and secondary faulting.

The Oak Ridge Mountains and surrounding vicinity are underlain by thousands of feet of sediments that rest unconformably on igneous and metamorphic basement rock. With respect to the near-surface geologic conditions, the southern piedmont slopes of the Oak Ridge Mountains are generally underlain by bedrock assigned to the Pleistocene-age Saugus Formation (Dibblee and Ehrenspeck, 1992). Other regional maps have also identified these same deposits as Pleistocene-age older alluvium. The Saugus Formation is terrestrial in origin and is believed to have largely been deposited by the ancestral Santa Clara River. Levi and Yeats (1993) utilized magneto-stratigraphy in the nearby Santa Susana Mountains to estimate the lower age of the Saugus at 2.3 million years old (Ma) and the upper age at 400 to 500 thousand years old (Ka). Locally, the discovery of a mammoth during grading for Tract 5054 (Moorpark Mammoth – see Figure 3) has provided a biostratigraphic age of 850 Ka to 780 Ka for the upper Saugus Formation in the immediate Site vicinity (Wagner et al., 2007). The Saugus Formation is generally overlain by late Pleistocene- to Holocene-age alluvial and colluvial deposits within the canyon areas and small tributary drainages. The location of the site and relation to the regional geology is shown the Regional Geologic Map, Figure 2.



3.2 GEOLOGIC UNITS

3.2.1 General

Based on our review and field investigation work, Pleistocene-age sediments assigned to the Saugus Formation underlies the gentle- to steep-sloping hills and is exposed in various cuts within the property. Previous studies by Gorian had also refereed to this same unit as older alluvium. The Saugus Formation is generally overlain by a thin mantle of topsoil. Late-Pleistocene to Holocene-age alluvial and colluvial deposits are also present within the canyon areas and small tributary drainages. Artificial fill materials are also locally present throughout the site. Descriptions of the geologic units are provided in the following sections. The approximate distribution of the geologic units is illustrated on the enclosed Geotechnical Map, Plates 1 & 2 and on our Geologic Cross-Sections, Plates 3 and 4. Descriptions of the geologic units encountered within the site are provided in the following sections and are presented in detail on the exploration logs by this firm in Appendix A and in the exploration logs by Gorian in Appendix C.

3.2.2 Artificial Fill (Af)

Artificial fill materials were encountered in our exploratory excavations and identified during our field mapping throughout the site. These fills are generally associated with drainage berms, access roads, and various above- and below-ground modifications that were made to the property in association with the site's previous use. More recent end-dump fills were also locally encountered on the site. The fill materials encountered are generally comprised of locally-derived brown to dark brown and red brown clayey sand and sandy clay. These materials are typically damp to moist, loose to medium dense / soft to stiff, and contain scattered gravels and cobbles. The artificial fill materials encountered in our exploratory trench T-4 in a drainage area located in the northeasterly portion of the site also contained abundant construction debris and other assorted trash.

N

REGIONAL GEOLOGIC MAP

From: Dibblee, T.W., and Ehrenspeck, H.E., ed., 1992, Geologic map of the Moorpark quadrangle, Ventura County, California: Dibblee Geological Foundation, Dibblee Foundation Map DF-40, scale 1:24,000.

NOT TO SCALE

FIGURE 2

The artificial fills associated with the drainage berms and access roads that extend throughout the site are up to 5 feet thick. Fills encountered within buried drainages identified in the northwesterly portions of the site and locally in a drainage in the northeasterly portion of the site are up to as much as 13 feet thick. Only those fills of significant thickness are shown on the Geotechnical Map, Plates 1 and 2.

3.2.3 Topsoil (No Map Symbol)

A thin veneer of topsoil is generally present in the upper 3 to 5 feet of the surface within the areas trenched. The topsoil is generally formed in-place by weathering of the underlying units and has been substantially disturbed from ploughing. The topsoil is generally comprised of very dark brown to very dark gray clayey sand and sandy clay that is typically damp to moist, loose / soft to medium stiff, and contains scattered gravel and roots. The topsoil was also observed to be moderately porous and have local, poorly-developed blocky ped structures where not completely disturbed.

3.2.4 Colluvium (Qcol)

The colluvium is generally comprised of brown to dark brown and reddish-brown sandy clay, clayey sand and silty sand. The colluvial materials are typically damp to moist, soft to medium stiff / loose to medium dense, moderately porous, and have slightly- to moderately-developed blocky ped structures with clay films and carbonate on ped surfaces. A trace to some gravel is present within colluvium materials. The colluvial deposit measured up to 14 feet in thickness within the center of the drainages.

3.2.5 Alluvium (Qal)

The alluvium was encountered within both wide and narrow drainage channels across the site. The alluvium is encountered within narrow drainages generally comprised of light brown to dark brown silty sand, clayey sand, and sand within the upper 15 to 18 feet and light brown to reddish brown silty sand at depth. Alluvial material in narrow drainages is typically medium dense with an occasional layer of loose material at depth and are dry to moist. These materials generally become reddish brown in color at depth, are porous throughout the deposit, and contain pores throughout the deposit. Alluvium in narrow drainage channels also locally contains increased deposits of sandy material and varying abundance of gravel.

Alluvial material encountered within the wide drainage channels generally consists of silty sand, clayey sand, gravelly sand and sand, with occasional interbeds of sandy clay, clay with sand, and clay. The sandy material is generally of various shades of brown, dry to moist, and loose to dense. The upper portion of the alluvial material is typically darker brown in color, lower in moisture content, and less dense. The fine-grained materials are generally dark brown to brown, moist, and medium stiff to hard. Coarse-grained gravelly material is typically found at the base of the alluvial layer.

3.2.6 Bedrock: Saugus Formation (Qs)

The bedrock materials encountered onsite are assigned to the Saugus Formation. This unit, which was also identified as older alluvium in some of the previous work by Gorian, generally consists of various shades of brown interbedded sandstone and siltstone with occasional conglomerate beds and lenses. In general, the bedrock materials are dry to moist and moderately hard to locally very hard particularly within the finer-grained well-indurated stratum. The near surface bedrock materials are generally moderately to extremely weathered with scattered krotovinas and roots and no visible structure.

Depositional features observed within the Saugus Formation include cross bedding, graded bedding, channel scours and fills, and lateral facies changes typically resulting in interfingered deposits.
Soil development features observed within the near surface Saugus Formation include local blocky ped structures, carbonate development, iron and manganese oxide staining, and siliceous cemented horizons. Sub-horizontal, laterally-discontinuous, closely-spaced, clay-rich laminations or lamellae (termed "Bt lams" in this report) were also observed within the sandier units. The Bt lams are easily distinguished from the parent material by their slightly darker and more oxide stained characteristics.

3.3 BEDDING STRUCTURE

As previously discussed, the Saugus Formation is terrestrial in origin and is believed to have been largely deposited by the ancestral Santa Clara River. As such, bedding structure in the Saugus Formation appears to be largely dominated by local depositional features (i.e. cross bedding, channel scours and fills, and interfingering structures) resulting in bedding attitudes that appear to dip at shallow angles in all directions. However, from a regional perspective, the site is located on the southeast flank of the Moorpark Anticline and the bedrock exposures in some of the long fault trenches excavated by this firm and by Gorian, suggest that overall bedding structure within the site generally dips at very shallow angles (typically ~3-8 degrees) to the south. Some local warping of the bedding structure was also evident in our fault trench FT-1 in the northeasterly portion of the site where a broad east-west trending anticlinal fold was encountered. Some of the data collected from the borings by this firm and Gorian may also suggest local warping of the bedding structure in other areas of the site. However, this could not be confirmed from the limited exposures.

The bedding structure depicted on the Geologic Cross-Sections, Plates 3 and 4, represent the general orientation of the bedding structure. Local warping and depositional features are not indicated at this time.

3.4 FAULTING

Based on our site-specific fault study for the site, which included a review of the previous fault trenching by Gorian, there are no active faults within or immediately adjacent the site. The site is also not within an "Earthquake Fault Zone" as defined by the State of California in the Alquist-Priolo Earthquake Fault Zoning Act. The closet know active faults to the site are the Oak Ridge fault, located approximately 5.5 miles northwest of the site, and the Simi-Santa Rosa fault, located approximately 1.5 to 2 miles southeast of the site.

Some minor faults (also referred to as shears) were encountered within the Saugus Formation in our exploration trench FT-1 during our fault study as well in some of our exploratory borings for this investigation. These faults generally strike in a east-west direction and dip at shallow degrees to the north and south. A more detailed discussion of faulting at the site is provided in a separate report by this firm (Albus-Keefe & Associates, Inc., April 3, 2019, Revised dated June 3, 2019).

3.5 LANDSLIDES

Based on this investigation and our review of the referenced publications, no landslides have been identified within or adjacent the subject site. No evidence of mudflow or other forms of surficial failures, other than some minor erosion (rutting) on some the existing cut slopes within the site, were noted within or adjacent the subject site.

3.6 GROUNDWATER

Groundwater was encountered in our exploratory boring B-3 in the southern portion of the site at a depth of 41.7 feet. The groundwater occurred within the Saugus Formation. During our fault investigation of the site, minor groundwater seepage was also locally encountered within our fault trenches at the base of some of the sandy channel scours within the Saugus Formation at shallow depths. The groundwater encountered in our fault trenches was attributed to the recent rainstorms that occurred prior to and intermittently during our fault study. The areas where seepage was noticed is shown on our enclosed Trench Logs, from our referenced fault report. Gorian also encountered ground water in their exploratory borings in the southernly portion of the site during their previous studies. The groundwater generally occurred at depths varying from 15 feet to 45.5 feet, depending on their location.

A complete summary of the groundwater depths and elevations encountered in borings by this firm and Gorian are provided in Table 3.1. Borings B-21, B-23, B-29, and B-32 by Gorian in 2000 were also converted to monitoring wells. For these borings, Table 3.1 includes groundwater level data from one or two readings in addition to the reading obtained on the drilling date. On April 11, 2019, our office also obtained a groundwater depth reading at B-23, the only monitoring well installed by Gorian (2000) that we could locate. Our reading was very close to earlier readings at this well, going back to 2000. This similar water level was despite significant precipitation in late 2018 and early 2019. This would suggest that groundwater levels have not changed substantially in this area over the years.

As summarized in Table 3.1, groundwater occurs primarily within the southerly portion of the site. Groundwater elevations suggest that ground water within the onsite drainages in the southerly portion of the site flows toward the south and then flows westerly within the alluvial soils in the broader Simi Valley at the southern margin of the site.

In addition to our review of the groundwater data from the various exploratory borings within the site, we reviewed the California Department of Water Resources database through the referenced link to assess the historical groundwater level data in the vicinity of the site. Three wells were located in the general vicinity of the site. One well located at the southeast corner of the site (just north of the intersection of Poindexter Avenue and Gisler Avenue) had historical groundwater data available from mid-1975 to late 2010 (with a four-year gap from 1985 to 1989). From 1975 to 1985, groundwater level rose from a depth of 138 feet to 37 feet below ground surface. From 1989 to 2005, groundwater level fluctuated between the depths of 40 and 27 feet, and then stabilized at a depth of about 27 feet through the end of data collection in December 2010. A second well located southwest of the site, which had only historical groundwater data only available from approximately 1975 to 1977, recorded a groundwater depth of about 337 feet. A third well located north of the site, which also had limited historical groundwater data from 1975 to 1985 recorded a groundwater level at a depth of about 590 ft below the ground surface.

TABLE 3.1
GROUNDWATER LEVEL DEPTH AND ELEVATION

Boring Number	Date	Ground Surface Elevation[(1)] (ft, MSL)	Groundwater Depth (ft)	Groundwater Elevation (ft, MSL)	Reference
B-3	8-19-2018	506	41.7	464.5	This Report
B-21	5-18-2000	501	35	465.5	Gorian (2000b)
	6-15-2000	501	33.7	466.8	Gorian (2000b)
	12-8-2008[(2)]	501	28.5	472	Gorian (2009b)
B-22	5-19-2000	501	30	470.5	Gorian (2000b)
B-23	5-19-2000	490	25	465	Gorian (2000b)
	6-15-2000	490	23	467	Gorian (2000b)
	12-8-2008[(2)]	490	22	468	Gorian (2009b)
	4-11-2019[(3)]	490	24	466	AKA Reading
B-24	5-22-2000	524	45.5	478.5	Gorian (2000b)
B-28	5-23-2000	498	42.5	455.5	Gorian (2000b)
B-29	5-23-2000	490	35	455	Gorian (2000b)
	6-15-2000	490	29	461	Gorian (2000b)

B-31	5-24-2000	494	45	448.6	Gorian (2000b)
B-32[(4)]	5-24-2000	483	35	448	Gorian (2000b)
	6-15-2000	483	32	451	Gorian (2000b)
B-13	11-22-1993	481	23	458.4	Gorian (1994)
B-14	11-22-1993	479	15	464.3	Gorian (1994)

Notes:
1) Ground surface elevations reported in this table are based on the topographic data shown on Plate 1 and 2 and might be different from the header of the related Gorian boring logs.
2) The date reported here (12-8-2008) is based on the field investigation in the referenced report and can be a few days different from the actual groundwater level reading date.
3) Groundwater depth reading of 4-11-2019 at B-23 was performed by our office. The remaining three monitoring wells (B-21, B-29, and B-32) could not be located on this date.
4) The monitoring well B-32 could not be found on 12-8-2008.

According to the referenced Seismic Hazard Zone Report for the Moorpark Quadrangle, historically high groundwater depths is 15 feet along the main westerly drainage course along the southerly margin of the site and the large southerly drainage course at the westerly margin of the site.

4.0 ANALYSES

4.1 SEISMICITY

We have performed probabilistic seismic analyses utilizing the web-based U.S. Seismic Design Maps web application by the U.S. Geological Survey (USGS). We obtain a PGA of 1.055g in accordance with Figure 22-7 of ASCE 7-10. The site amplification factor, F_{PGA}, for Site Class D in this range of PGA is 1.0. Therefore, the PGA_M = 1.0 x 1.055g = 1.06g. The mean event associated with a probability of exceedance equal to 2% over 50 years has a moment magnitude of 6.9 and the mean distance to the seismic source of 5.0 miles.

4.2 SETTLEMENT

Existing topsoil, colluvial, and alluvial soils are moderately compressible and often prone to hydrocollapse (consolidation upon wetting). As such, these materials are anticipated to be removed and recompacted. Since these materials will be placed as fill at slightly over optimum, primary consolidation of fill materials due to self-weight is anticipated to occur as the material is placed and compacted. Remaining settlement will then be the result of secondary consolidation of the fill from self-weight. This assumes that secondary settlement due to reloading of the underlying Saugus formation will be negligible due to the natural over-consolidated conditions and induration.

Based on the relationship proposed in the NAVAC (1982) Design Manual 7.1, the coefficient of secondary consolidation may be estimated from the following equation:

$$H_{sec} = C_{\alpha}(H_t) log \frac{t_{sec}}{t_p}$$

Where:

Hsec = Settlement from secondary Consolidation
Cα = coefficient of secondary consolidation
Ht = Thickness of the compressible stratum
tsec = time of structure design life
tp = Time of completion of primary consolidation

The coefficient, Cα, is provided on Figure 16 of the manual. Using a typical post-compacted moisture content of 17%, we obtain a Cα equal to 0.0017. The maximum depth of fill after removal of all soil materials and filling to proposed grade is estimated to be about 85 feet. Taking the design life to be 50 years, we obtain a total secondary settlement of about 5 inches assuming a tp of 1 month.

Of more particular interest is the differential settlement. The natural slopes within the drainages of the project are typically inclined at about 3:1 (H:V). If we assume a maximum tolerable differential settlement of 0.5 inches over 30 feet, we can use the above equation to back-calculate the time required to wait until achieving this differential. Over a horizontal distance of 30 feet, the fill thickness will

change by 10 vertical feet. Using this thickness for the fill, we obtain a time of 2 months to achieve a remaining differential settlement of 0.5 inches over 30 feet.

4.3 LIQUEFACTION

Engineering research of soil liquefaction potential (Youd, et al., 2001) indicates that generally three basic factors must exist concurrently in order for liquefaction to occur. These factors include:

- A source of ground shaking, such as an earthquake, capable of generating soil mass distortions.
- A relatively loose silty and/or sandy soil.
- A relative shallow groundwater table (within approximately 50 feet below ground surface) or completely saturated soil conditions that will allow positive pore pressure generation.

The liquefaction susceptibility of the onsite soils was evaluated by analyzing the potential concurrent occurrence of the above-mentioned three basic factors. The liquefaction evaluation for the site was completed under the guidance of Special Publication 117A: Guidelines for Evaluating and Mitigating Seismic Hazards in California (CDMG, 2008).

These analyses were performed using data from three hollow stem borings that encountered groundwater. These are boring B-3 (this report), and borings B-21 and B-23 (Gorian, 2000). For borings B-3 and B-21, groundwater depths of 33 and 28.5 feet, respectively were used which correspond to an elevation 472 feet (MSL). A groundwater depth of 22 feet was used for liquefaction analysis of B-23, corresponding to an elevation of 468 feet (MSL).

Blow counts obtained from the larger California ring-lined sampler were corrected in the analyses (SCEC, 1999). Fine-grained soils that do not have a Plasticity Index (PI) less than 12 and field moisture contents greater than 85% of liquid limit (LL) or soils with corrected blow counts greater than 30 blows per foot were assumed to be not susceptible to liquefaction.

Appendix D includes a printout of the liquefaction analyses for these three borings. Based on our analyses, in Gorian borings B-21 and B-23 (Plates D-2 and D-3) all layers between groundwater and a depth of 50 (bottom depth for liquefaction analysis) have factors of safety below 1.3 and as such, are prone to liquefaction during a strong ground motion event. In boring B-3 (Plate D-1) the large penetration resistance (SPT blow count), rule out the potential for liquefaction.

4.4 SLOPE STABILITY

Stability analyses were performed using the computer program SLIDE to evaluate the gross stability of existing, proposed cut, and proposed fill slopes supporting the project. Both static and seismic stability were evaluated. Among various slope stability methods available in SLIDE, Generalized Limit Equilibrium (GLE) method was used in all these analyses. Block, non-circular, and circular sliding surfaces were utilized as deemed appropriate.

These analyses were performed for three cross sections C-C', E-E', and F-F' (Plates 3 and 4) deemed to represent the most critical conditions across the proposed development. Cross section C-C' involves a 66-foot-high cut at 1.6H:1.0V slope and is the steepest proposed cut slope. Cross section E-E'

involves approximately 75 feet of fill and is the highest fill slope. Cross section F-F' represents the most critical existing off-site slope approximately 85 feet in height.

Three different geotechnical materials are included in these cross sections. These are the proposed fill, alluvium, and Saugus formation. Data from our field investigation and laboratory tests, as well as those from various referenced reports from Gorian were reviewed to assess shear strength parameters representing these materials in SLIDE models. Shear strength parameters used in slope stability analyses are summarized in Table 4.1.

TABLE 4.1
SUMMAY OF SHEAR STRENGTH PARAMETERS
FOR SLOPE STABILITY ANALYSES

Material	Unit Weight (pcf)	Friction Angle (degrees)	Cohesion (psf)
Proposed Fill	120	29.0	100
Alluvium	120	25.0	0
Saugus (cross-bedding)	120	34.5	480
Saugus (along-bedding)	120	22.0	0

Properties of the proposed fill were assigned based on the average ultimate strength values from direct shear test results on remolded samples from our work as well as Gorian's various reports (referenced).

The alluvial soils appear only in cross section E-E', close to the toe of the proposed fill slope. Correlations provided in NAVFAC (1982) between friction angle and N_{60} (Standard Penetration Test, SPT, blow counts corrected for hammer efficiency) from Boring log B-21 (Gorian, 2000) were used to assess the friction angle of in-place alluvium.

Because of the potential for clayey layers alternating with sandy layers, the Saugus formation was modeled as an isotropic material. The clay layers were conservatively assumed to exist in relatively continuous layers dipping at 3 to 8 degrees to the south as the predominant orientation of bedding structure. The strength parameters for the orientation along bedding (clay layers) were based on the ultimate shear strength parameters estimated from results of direct shear test on undisturbed specimens from clayey constituents of Saugus formation.

The Saugus formation was assumed to consist equally of cohesive and granular constituents. As a result, the cross-bedding shear strength parameters for this formation were determined as the average of the properties of cohesive constituents and granular constituents. For cohesive materials, peak shear strength parameters from direct shear test was used. For the granular portion, correlations with N_{60} as presented in NAVFAC (1982) were used.

As discussed earlier, liquefaction analyses using boring log B-21 (Gorian, 2000) that is very close to the southern part of cross section E-E' indicate a liquefaction potential below groundwater level. Close

examination of values of clean sand normalized SPT penetration resistance indicate the liquefiable layer between the depths of 29 and 50 feet can be subdivided into two sublayers. The first sublayer extends between the depths of 29 and 41 feet and has values of $(N_1)_{60\text{-}cs}$ ranging from 5 to 17. The second sublayer is below the depth of 41 feet with $(N_1)_{60\text{-}cs}$ in the range of 18 to 28. Using Figure 9.57 of Kramer (1996) the residual shear strengths of 150 and 800 psf were assigned to these two liquefied sublayers, respectively. These values are deemed conservative, particularly for the upper sublayer (depth 29 to 41 feet). The liquified residual shear strength parameters are assumed to be applicable to the post-seismic event. As a result, the related slope stability analyses considering liquefaction are performed without a pseudo-static loading condition.

Seismic slope stability analyses were performed using a pseudo-static method with the horizontal seismic coefficient K_{eq} = 0.15, estimated by following the guidelines in SP 117A. The Maximum Horizontal Acceleration (MHA) used in this approach is estimated from Peak Ground Acceleration (PGA=1.06g, Section 4.1 of this report), by taking into account configurations of the slope. The entire soil mass in a slope or within a potential failure block does not experiences the same acceleration at the same time. The higher the slope, the smaller MHA is relative to PGA. All of the three cross sections analyzed involve high slopes that justify the use of an MHA that is smaller than PGA. Furthermore, with increasing depth of potential sliding surface below the crest, MHA decreases. Figure 9 of Makdisi and Seed (1977) was used to estimate the ratio between MHA and PGA. A ratio of 0.35 is estimated from this figure, resulting in MHA = 0.35 x 1.06g = 0.37(g).

Figure 1 in SP 117A was used with tolerable displacement of 15 centimeters (cm) to estimate f_{eq} for this site. Using the magnitude and distance reported in Section 4.1, this figure results in f_{eq} = 0.4. As a result, $K_{eq} = f_{eq}$ x MHA = 0.4 x 0.37 = 0.15.

Results of our analyses are summarized in Table 4.2. Appendix E includes printouts of slope stability analyses of the program SLIDE that show details and results of these analyses. Results for block analyses of Section F-F' include plots of all failures as well as results filtered to only show failures with a factor of safety greater than 1.5 and 1.1 for static and seismic conditions, respectively (see Plates E-16 & E-18 in Appendix E).

5.0 CONCLUSIONS

5.1 FEASIBILITY OF PROPOSED DEVELOPMENT

From a geotechnical point of view, the proposed site development is considered feasible. Furthermore, we conclude the proposed development will not adversely impact the stability of adjoining properties. The adequacy and sufficiency of the preliminary findings provided herein should be further assessed based upon a review of the final grading and structural plans/details and engineering and geologic analyses. A final geotechnical investigation report should be prepared for design, permitting and construction to include recommendations for site development and mitigation of geotechnical factors. Key geotechnical issues that could impact the proposed site development are discussed in further detail in the following sections.

TABLE 4.2
SUMMARY OF SLOPE STABILITY ANALYSES

Type of Analysis (and Condition)	Cross Section C-C'	Cross Section E-E'		Cross Section F-F'
		Ordinary	Liquefaction	
Block (Static)	1.67 (Plate E-2)(1)	Not Needed		1.39/1.50(2) (Plate E-15 & 16)
Block (Seismic)	1.17 (Plate E-3)			1.08/1.11(2) (Plate E-17 & 18)
Non-Circular (Static)	Not Needed	1.60 (Plate E-7)	---	Not Needed
Non-Circular (Seismic)		1.16 (Plate E-8)	1.37 (Plate E-12)	
Circular (Static)	2.36 (Plate E-4)	1.62 (Plate E-9)	---	1.84 (Plate E-19)
Circular (Seismic)	1.8 (Plate E-5)	1.18 (Plate E-10)	1.62 (Plate E-13)	1.52 (Plate E-20)

Notes:
1) Plate numbers in Appendix E where the details of the slope stability analyses for this case is provided.
2) Second factor of safety is related to the minimum value obtained for searches behind the structural setback where buildings will be constructed.

5.2 GEOLOGIC HAZARDS

5.2.1 Ground Rupture

Results of our fault study, dated April 3, 2019 (revised June 3, 2019), indicate there is no evidence of "active" faulting, as defined by the State under the provisions of the Alquist-Priolo Earthquake Fault Zoning Act, within and/or immediately adjacent the site. Furthermore, the site does not lie within the bounds of a State of California "Earthquake Fault Zone" (EFZ) as defined by the Alquist-Priolo Earthquake Fault Zoning. As such, the potential for ground rupture due to a fault displacement beneath the site is considered very low.

5.2.2 Ground Deformation

Although no evidence of recent ground deformation was observed within our fault study , the site is located in an active tectonic regime associated with crustal shortening between the Oak Ridge and Simi-Santa Rosa fault systems. A significant earthquake on either the Oak Ridge or Simi-Santa Rosa faults could possibly result in minor ground deformation that can manifest as small-scale shear displacements or general ground tilting, particularly in the area of existing minor faults and folds. However, considering that faults and folds observed during our investigation have not experienced any discernable amount of movement during Holocene time, the probable magnitude of displacement during the life of the proposed structures would likely be extremely small. As such, mitigation measures for potential future ground deformation is not deemed necessary. Further discussion on this issue can be found in our referenced fault study report. The potential for ground deformation due to small-scale shear displacements can be re-evaluated during site grading to confirm the conclusions

presented herein. In the event that small-scale deformation is deemed to rise to a level that could impact site development, mitigation measures could readily be incorporated in the design of foundations for habitable structures to provide increased resistance to small-scale ground movements

5.2.3 Ground Shaking

The site is situated in a seismically active area that has historically been affected by generally moderate to occasionally high levels of ground motion. The site lies in relative close proximity to several active faults; therefore, during the life of the proposed improvements, the property will probably experience similar moderate to occasionally high ground shaking from these fault zones, as well as some background shaking from other seismically active areas of the Southern California region. Design and construction in accordance with the current California Building Code (CBC) requirements is anticipated to address the issues related to potential ground shaking.

5.2.4 Landsliding and Debris Flows

No evidence of historical landsliding was identified during this study nor was it reported by others. However, some areas of very steep terrain that will be supporting the proposed development within the southerly margin of the site are located in a State of California Landslide Zone. Conclusions regarding stability of existing slopes are addressed in Section 5.7.

The ascending slopes above the site margining the proposed development are generally mantled by topsoil. However, review of historical aerial photographs dating back to 1929 and recent field mapping of these slopes did not indicate any evidence of past surficial failures or mudflow events. We attribute this condition to the relatively gentle inclination of these slopes and the gradual transition of topsoil to Saugus formation materials. The gradual transition avoids the creation of a well-defined contact upon which failures may tend to form. We conclude the site is also at a low risk to mudflow and debris failures from adjacent natural slopes.

5.2.5 Tsunami and Seiches

The portion of the site to be developed is elevated approximately 500 feet above mean sea level and is located a substantial distance from a significant body of water. As such, the potential for hazards related to tsunami is considered very low. No sizable enclosed body of water is within the site or its vicinity. As result, the potential for hazards associated with seiches is non-existent.

5.3 GROUNDWATER

As discussed above, groundwater was encountered between the depths of 15 and 46 feet below current ground surface during site investigations. All the exploratory borings that encountered groundwater were in the southern margin of the site. Historical data suggests the depth to groundwater in this area is unlikely to vary significantly from current levels under current site conditions for the short term (next several years). This condition is generally not anticipated to result in any adverse conditions for site development provided construction will not require excavations below groundwater such as deep utilities.

Groundwater conditions in the future may vary more significantly in the long term as a result of seasonal variations of rainfall, regional groundwater withdraw, and future site development. Historical

data indicates that variations in groundwater depth in the southern margin of the site have varied by at least 100 feet over the last several decades. Data over the last 30 years has suggested a more consistent groundwater level. Future site development may lead to a minor rise in the groundwater levels in this area as irrigation water infiltrates into the ground and migrates to the lower elevations to the south. We do not anticipate such changes to result in detrimental effects on proposed site development or adjacent properties.

Proposed engineered fills will be derived from onsite materials which contain both fine-grained and granular materials. Fills may create conditions that form thin, perched groundwater conditions in the future due to finer-grained soils creating aquitards below the granular materials. If surface fills are comprised of granular soils but are underlain by fine-grained soils within the upper few feet, such perched groundwater conditions could impact site development. Detrimental effects could include excessive moisture vapors in structures, seepage or excessive moisture in retaining walls, and seepage or excessive moisture in local areas of low elevation. Such adverse conditions can be mitigated by careful consideration of placing fills to avoid creating such conditions as well as providing appropriate subdrainage and waterproofing in retaining walls. Specific details of these mitigation steps can be determined during review of final grading plans and during site construction.

The Saugus formation in comprised of interlayers of fine-grained and granular materials. These layers are structurally inclined at low to moderate angles. Although the general dip of the formation is at low angles to the south, localized variations in dip angle and direction can occur. The presence of the finer-grained layers can act as aquitards that can cause the formation of thin, perched groundwater within the Saugus formation. This perched groundwater may occur in proximity to slopes, retaining walls, and other areas of grade differential. If such a condition forms due to infiltration of rainfall or irrigation, groundwater may seep out of slope faces, retaining walls, and points of low elevation. Potential adverse conditions created by such perched conditions can be mitigated during construction through installation of stability fills on cut slopes, installation of subdrains, and installation of subdrains and waterproofing on retaining walls. Specific details of these mitigation steps can be determined during review of final grading plans and during site construction.

5.4 SOIL EXPANSION

Based on our field exploration and laboratory test results, the geotechnical materials within the site are anticipated to generally possess Very Low to Medium expansion potential. One of the expansion test results in Gorian (2000b) falls in the lower range of High expansion potential (Boring B-B, depth 25 feet, EI=94) and is for a sample from the Saugus Formation. Expansive soils can cause damage to overlying structures and improvements when they undergo heave from wetting or shrinkage from drying. This condition can be mitigated through the design and construction of foundations, slabs on grade, and other elements of site development in consideration of this condition. General mitigation methods are discussed in Section 6.0 under the respective design elements.

5.5 STATIC SETTLEMENT

As indicated by our analyses in Section 4.2, engineered fills up to 85 feet in depth are anticipated and will undergo long-term settlement due to self-weight of the fill. The placement of fills will result in raising the grade by up to about 50 feet over areas underlain by Saugus formation materials. The

secondary consolidation of Saugus formation materials due to reloading by this change in grade is anticipated to be negligible due to the natural over-consolidated conditions and induration of the formation. Therefore, settlement due to consolidation of the underlying Saugus formation is anticipated to be negligible. Footings will also undergo some settlement due to loading from the superstructure weight. Much of the weight causing foundation settlement will be in place before sensitive finishes are placed on the structures. In consideration of the above factor and light loading anticipated, we have assumed the magnitude of settlement of footings due to structural loading is negligible and was not evaluated. Therefore, settlement in structures and site improvements will only be dictated by settlement of fill soils due to self-weight.

From our analyses, we have estimated the total settlement of the ground surface will be up to approximately 5 inches over a period of 50 years. The associated differential settlement is estimated to be approximately ½ inch over 30 feet after a period of 2 months following fill placement. Although the total settlement is greater than customarily considered, the differential settlement will primarily dictate project performance. The residential structures are generally considered the most sensitive to differential settlement and the estimated magnitude is within generally acceptable limits provided construction of the buildings is delayed at least 2 months following grading. Long-term settlement may result in causing elongation and associated tension in underground utilities that cross the drainages if they are constructed shortly after grading. Design and construction of underground utilities will require consideration of this effect. If certain utilities will be sensitive to this condition, mitigation could include delay in constructing such utilities across deep fills or providing sections that will accommodate the tensile force through jogs, flexible joints, and slip joints. Specific recommendations can be developed during project design.

5.6 LIQUEFACTION

As indicated by the results of our analyses in Section 4.3, portions of the site materials are prone to liquefaction during a strong ground motion event. During a liquefaction event, these materials will likely undergo seismic consolidation that could result in deformation of the ground surface supported by these soils. The deformation could be on the order of a few inches. As currently planned, no residential structures would be supported by these materials provided all colluvial and alluvial soils are removed below proposed residential structures. Therefore, potential adverse conditions related to liquefaction and related seismic settlement of habitable structures can be readily mitigated as recommended in Section 6.1.5.

Soils that undergo liquefaction also exhibit a loss in shear strength following the ground motion event. Such soils will be supporting some proposed fill slopes along the southern margin of the site. The potential for destabilization of constructed slopes due to liquefaction is addressed in Section 5.7.

5.7 SLOPE STABILITY

As discussed earlier in this report under Section 4.4, slope stability analyses were performed using the computer program SLIDE. The analyses were performed for three cross sections throughout the site that are deemed to represent the most critical conditions in terms of existing slopes, proposed fill slopes, and proposed cut slopes. These conditions are represented by cross sections C-C', E-E', and F-F' (Plates 3 and 4). Results of our analyses indicate that proposed cut and fill slopes (sections C-C'

and E-E') are expected to exhibit static and seismic factors of safety greater than 1.5 and 1.1, respectively. These factors of safety are considered adequate for the proposed site development.

Analyses of the existing slope in Section F-F' indicate factors of safety less than 1.5 and 1.1 for static and seismic conditions, respectively. These factors are below the generally accepted minimums for proposed site development. Our analyses also indicate the portions of these slopes that have substandard factors of safety are located relatively near the face of the slope. As such, this condition can be mitigated by providing a structural setback from the tops of these slopes such that appropriate factors of safety are obtained for support of the proposed development. Once more finalized site development plans are prepared, specific setbacks can be determined through additional engineering analyses. From a preliminary standpoint, our analyses indicate that a setback from the top of slope equal to approximately ⅔ of the total slope height will provide the necessary setback.

5.8 EXCAVATION AND MATERIALS CHARACTERISTICS

Based on the results of our subsurface exploration, the onsite materials should be readily excavated by conventional heavy earthmoving equipment. Excavations within some of the finer-grained, well-indurated bedrock materials may generate oversized rock materials that will require reduction in size or hauling off site. Specific recommendations are provided in Section 6.1.10.

With respects to future trenching for utilities etc., some of the finer-grained, well-indurated bedrock materials may be locally difficult to excavate with an excavator and standard backhoe. This condition can be mitigated by overexcavating bedrock materials within future streets to a depth below invert grades as discussed in Sections 6.1.6.

Significant portions of the site materials have moistures below optimum moisture content. As such, recompaction of these materials is anticipated to require the addition and blending of water to be suitable for use as compacted fill. The deeper alluvial materials in the major canyon areas, however, are locally very moist to wet and soft and may require special handling (excavator and top-loading). Dewatering may also be required if excavations will extend below groundwater levels. Recompaction of these materials is also anticipated to require drying back and/or blending with dryer materials in order to be suitable for use as compacted fill. Specific recommendations for removal and recompacting these materials should be provided based on actual conditions encountered during grading.

5.9 SHRINKAGE, BULKING AND SUBSIDENCE

Volumetric changes in earth quantities will occur when excavated onsite soil materials are replaced as properly compacted fill. The volume change of excavated materials upon recompaction is expected to vary with material types, depth of excavation, in-situ density, and compaction techniques and effort. Based on laboratory testing and our experience with similar projects, the following estimates of shrinkage and bulking are summarized in Table 5.1.

TABLE 5.1
ESTIMATES OF SHRINKAGE AND BULKING

MATERIAL	VOLUME CHANGE	SHRINKAGE/BULKING
Artificial Fill	10% to 20%	Shrinkage
Topsoil (no map symbol)/Colluvium (Qcol) /Alluvium (Qal)	5% to 11%	Shrinkage
Bedrock (Saugus Formation)	0% to 5%	Bulking

The above estimates of shrinkage and bulking are intended as an aid for project engineers in determining earthwork quantities. However, these estimates should be used with some caution since they are not absolute values. Contingencies should be made for balancing earthwork quantities based on actual shrinkage and bulking and ground subsidence that occur during grading. Processing of surfaces prior to placement of new fills is not anticipated to result in measurable subsidence and may be ignored.

6.0 RECOMMENDATIONS

6.1 EARTHWORK

6.1.1 General Earthwork and Grading Specifications

All earthwork and grading should be performed in accordance with applicable requirements of Cal/OSHA, applicable specifications of the Grading Codes of City of Moorpark, California, in addition to recommendations presented herein.

6.1.2 Pre-Grade Meeting and Geotechnical Observation

Prior to commencement of grading, we recommend a meeting be held between the developer, City inspector, grading contractor, civil engineer, and geotechnical consultant to discuss the proposed grading and logistics. We also recommend that a geotechnical consultant be retained to provide soil engineering and engineering geologic services during site grading and foundation construction. This is to observe compliance with the design specifications and recommendations, and to allow design changes in the event that subsurface conditions differ from those anticipated. If conditions are encountered that appear to be different than those indicated in this report, the project geotechnical consultant should be notified immediately. Design and construction revisions may be required.

6.1.3 Site Clearing

All existing improvements, vegetation and other deleterious materials should be removed from the areas to be developed. The project geotechnical consultant should be notified at the appropriate times to provide observation services during clearing operations to verify compliance with the above

recommendations. Voids created by clearing should be left open for observation by the geotechnical consultant. Should any unusual soil conditions or subsurface structures be encountered during site clearing or grading that are not described or anticipated herein, these conditions should be brought to the immediate attention of the project geotechnical consultant for corrective recommendations as needed.

6.1.4 Seepage Pit and Water Well Abandonment

Seepage pits and water wells encountered during future site grading should be properly destroyed or abandoned in accordance with the requirements established by the governing agencies as well as recommendations made in the field by the project geotechnical consultant. As previously discussed, there are at least 15 water wells that have been drilled throughout the site. The approximate locations of known water wells are shown on the enclosed Geotechnical Map, Plates 1 & 2. The current status of most of these wells is unknown (e.g. active, abandoned, destroyed), but at least 3 are believed to be intact.

6.1.5 Ground Preparation

In general, all existing exploratory trench backfill, artificial fill, topsoil, colluvium, alluvium, and weathered bedrock are considered unsuitable for support of proposed structural fills and site development and should be removed through excavation or benching to expose competent bedrock (Saugus formation). However, removal of alluvial materials may be limited where groundwater is encountered and beneath proposed roadways and detention basins. In general, removal of alluvial materials may be limited to a depth that is 3 feet above groundwater. Removal of alluvial materials for roadways and detention basins may be limited to 3 feet below finish grade.

Removals for the balance of the site which include areas influencing the residential building pads are anticipated to vary from as little as 3 feet to as much as 50 feet below the existing ground surface. Actual ground preparation recommendations should be determined by the geotechnical consultant based on future grading plan reviews and analyses as well as conditions exposed during site grading.

6.1.6 Building Pad Capping

Transition Pads: Future rough grading will create cut/fill transitions or shallow fill conditions within building pads following removal of unsuitable materials. In general, transition pads should be overexcavated at least 5 feet below finish pad grades and replaced with a compacted fill blanket. The overexcavation should extend across the entire pad or at least 5 feet beyond the outside edge of the proposed footings. The bedrock/fill contact should be no steeper than 2 to 1 (H:V). Where the overall gradient is steeper, the contact should be laid back to a maximum overall gradient of 2 to 1 (H:V). Where cuts for transition pads expose fine-grained materials that could create an aquitard, the undercut should either be sloped at a minimum gradient of 5% toward the street or the lot should be capped with fill similar to the underlying formational materials.

Actual transition pad capping recommendations should be determined by the geotechnical consultant based on future grading plan reviews and analyses as well as conditions exposed during site grading. A typical transition lot capping detail is provided on Plate F-1 in Appendix F.

Cut Pads: Future rough grading will create cut pads. Cut pads should be brought to near rough grade then observed by the geotechnical consultant. If significant differential bedrock materials are exposed, the pad should be generally overexcavated at least 5 feet below finish pad grades and replaced with a fill blanket. The overexcavation should extend across the entire pad or extend at least 5 feet beyond the outside edge of the proposed footings. Where cuts for overexcavation expose fine-grained materials that could create an aquitard, the undercut should either be extended out to the street and sloped at a minimum gradient of 5% toward the street or the lot should be capped with fill similar to the underlying formational materials.

Actual cut pad capping recommendations should be determined by the geotechnical consultant based on future grading plan reviews and analyses as well as conditions exposed during site grading. A typical cut lot capping detail is provided on Plate F-2 in Appendix F.

6.1.7 Street Capping

Based on our subsurface exploration, some of the bedrock materials exposed within the streets could be locally very difficult to impossible to trench with an excavator and/or conventional backhoe equipment for the installation of future underground improvements. For ease of future trenching, the cut and shallow fill portions of the future streets can be overexcavated at least 18 inches below the invert of the deepest utility line where hard bedrock conditions may be encountered. The overexcavation should also consider future utility hook-ups to residences and any utilities behind curb. Actual street capping recommendations should be determined by the geotechnical consultant based on future grading plan reviews and conditions exposed during site grading A typical street capping detail is provided on Plate F-3 in Appendix F.

6.1.8 Canyon Subdrains

Where practical, canyon subdrains are recommended within all canyon areas following removals. The subdrains should consist of a 6-inch-diameter PVC schedule 40 perforated pipe or 8-inch-diameter PVC schedule 40 perforated pipe when over 500 feet in length. The pipe should be embedded in 9 cubic feet per linear foot of 3/4-inch gravel wrapped in Mirafi 140N, or equivalent. The subdrain, where possible, should be placed on the bottom of the canyon cleanout area. Within the lower portions of the canyons, the subdrain may be placed on a bench in the sidewall of the canyon, above the cleanout bottom, to permit the subdrain to daylight. The subdrain should be set to drain generally at a minimum gradient of 1 percent. The outlets should consist of similar solid pipe and should daylight approximately 2 feet above the toe of slope or into a storm drain device. The necessity and locations of the canyons subdrains should be determined based on future grading plans reviews and actual site conditions during rough grading. A typical canyon subdrain detail is provided on Plate F-4 in Appendix F.

6.1.9 Scarification

Prior to placement of compacted fill, the exposed ground should generally be scarified to a depth of 6 inches, moisture conditioned to at least 110 percent of the optimum moisture content, then compacted to at least 90 percent of the maximum dry density determined in accordance with ASTM D 1557. The geotechnical consultant should provide final recommendations for scarification, based on actual conditions exposed during grading.

6.1.10 Fill Placement

In general, materials excavated from the site may be used as fill provided they are free of deleterious materials and rocks greater than 12 inches in maximum dimension. Within the upper 5 feet of building pads, fill materials should not contain rocks greater than 6 inches in maximum dimension. Materials greater than 12 inches in diameter that cannot be reduced should be hauled offsite or placed in deeper fill as discussed in Section 6.1.10. Fill should be placed in lifts no greater than 8 inches in loose thickness, moisture-conditioned to 110 to 125 percent of optimum moisture content, and compacted in place to at least 90 percent of the maximum dry density determined in accordance with ASTM D 1557 laboratory standard. Each lift should be treated in a similar manner. Subsequent lifts should not be placed until the project geotechnical consultant has approved the preceding lift. When placing fill on ground sloping steeper than 5:1 (H:V), vertical benches should be excavated into the adjacent slope.

To mitigate the potential for creating differential expansion potentials in the building pads, the upper 3 feet of the building pads should be capped with a uniform blanket of fill possessing similar engineering properties.

6.1.11 Over-sized Materials

Rocks over 12 inches in diameter should be reduced in size where practical and incorporated within the fill materials provided they are mixed with granular materials and spread throughout the fill to eliminate nesting. Rocks greater than 12 inches but less than 3 feet in diameter may be placed within engineered fills at least 10 feet below proposed grades as well as at least 18 inches below deepest utilities within streets, as presented on Plate D-5 in Appendix D. Rocks greater than 3 feet in diameter that cannot be reduced in size should be removed from the site.

6.1.12 Fill Slopes

Fill slopes (fill over natural slopes, fill over cut slopes) should be constructed with a keyway having a minimum width of 12 feet and a minimum embedment of 2 feet into competent earth unit. A minimum width of 10 feet of fill should be maintained throughout fill slope construction to prevent sliver fills and cut/fill transitions within finished slopes. Details for fill slope construction are presented on Plate F-6 in Appendix F.

Where practical, fill slopes should be constructed by over filling and trimming back to a compacted core. The face of slopes that are not over-built should be backrolled with a sheepsfoot roller at least every 4 vertical feet of slope construction. The process should provide compacted fill to within 12 inches of the slope face. Finished slopes should be track-walked with a small dozer or rolled with a vibratory compactor and grid roller in order to compact the slope face. The slope face materials will tend to dry out prior to final face compaction. As such, the addition of water to the slope face will likely be required prior to compaction to achieve the required compaction at the time of slope face compaction.

6.1.13 Cut Slopes

All cut slopes into bedrock should be inspected at intervals not exceeding 10 feet during grading by an engineering geologist, to evaluate the competency of the slope. Heavy ripping should be designed in a manner as to minimize disturbing the bedrock below proposed slope grades.

6.1.14 Stabilization Fills

Cut slopes exposing rock that exposes locally-adverse geologic conditions, expose sandy bedrock materials that are friable and prone to erosion, or where possible nuisance seepage issues could occur may require replacement with stabilization fill slopes. General details for stabilization fill slope construction are presented on Plate F-7 in Appendix F. However, specific recommendations should be provided by the geotechnical consultant during grading depending on the actual conditions exposed.

6.1.15 Slope Backdrains

Slope backdrains are generally recommended in all fill key excavations and stabilization fill slopes. The locations and necessity of the slope backdrains should be determined by the project geotechnical consultant in the field during rough grading. General details for slope backdrains are presented on Plate F-8 in Appendix F.

6.1.16 Import Materials

If earth materials are imported to the site in order to achieve the proposed grades, the proposed import soil should have a maximum particle size of 6 inches, have an Expansion Index less than 51 (per ASTM D4829), and have negligible soluble sulfate content. Import sources should be indicated to the geotechnical consultant prior to hauling the materials to the site so that appropriate testing and evaluation of the fill material can be performed in advance.

6.1.17 Temporary Excavations

Temporary construction slopes in site materials may be cut vertically up to a height of 4 feet provided that no adverse geologic conditions or surcharging of the excavations are present. Temporary slopes over 4 feet but less than 15 feet in height should be laid back at a maximum gradient of 1:1 (H:V) or properly shored. Excavations over 15 feet in height should be laid back at a maximum gradient of 1.5:1 (H:V) or properly shored. Excavations should not be left open for prolonged periods of time. The project geotechnical consultant should observe all temporary cuts to confirm anticipated conditions and to provide alternate recommendations if conditions dictate.

Where temporary excavations cannot accommodate proper layback or where surcharging occurs, slot cutting, shoring, underpinning, or other methods should be used. Specific recommendations for these options should be provided by the geotechnical consultant after specific design plans have been developed.

6.1.18 Settlement Monitoring

The site is anticipated to have fills up to as much as approximately 85 feet in thickness following removals. Fills over 50 feet in depth will generally require settlement monitoring. Settlement monument details are provided in Appendix F, Plate F-9. Location of settlement monuments will be based on future analyses as well as the as-built geologic conditions following future rough grading.

6.2 SEISMIC DESIGN PARAMETERS

For design of the project in accordance with Chapter 16 of the 2016 CBC, Table 6.1 below presents the seismic design factors.

TABLE 6.1
CBC 2016 SEISMIC DESIGN PARAMETERS

Parameter	Value
Site Class	D
Mapped MCE Spectral Response Acceleration, short periods, S_S	2.747
Mapped MCE Spectral Response Acceleration, at 1-sec. period, S_1	0.949
Site Coefficient, Fa	1.0
Site Coefficient, Fv	1.5
Adjusted MCE Spectral Response Acceleration, short periods, S_{MS}	2.747
Adjusted MCE Spectral Response Acceleration, at 1-sec. period, S_{M1}	1.424
Design Spectral Response Acceleration, short periods, S_{DS}	1.831
Design Spectral Response Acceleration, at 1-sec. period, S_{D1}	0.949

MCE = Maximum Considered Earthquake

6.3 PRELIMINARY FOUNDATION DESIGN RECOMMENDATIONS

6.3.1 General

The following recommendations are provided for preliminary design purposes. These recommendations have been based on the site materials exposed during our investigation, our understanding of the proposed development, and the assumption that the recommendations presented herein are incorporated into the design and construction of the project. Final recommendations should be provided by the project geotechnical consultant following review of final foundation plans as well as observation and testing of site materials during grading. Depending upon the design plans and actual site conditions, the recommendations provided herein may require modification.

6.3.1 Soil Expansion

Expansion potential of existing site materials is expected to vary from **Very Low** to **Medium**. As such, we are providing design values for foundation soils in three expansion potential categories. For very low expansion potential (Expansion Index, EI $\leq$ 20), recommendations on conventional footings and slabs on grade are provided. For low expansion potential (20 < EI $\leq$ 50) and medium expansion potential (50 < EI $\leq$ 75) foundation soils, recommendations on post-tensioned slabs on grade are given. Additional testing of site soils should be performed by the project geotechnical consultant to confirm the basis of these recommendations during site grading. At that time, additional testing may allow for alternate foundation designs for less expansive conditions if they are present for portions of the project.

6.3.2 Static Settlement

Provided rough grading is performed in accordance with the recommendations provided herein and based on the anticipated relatively light foundation loads, total and differential static settlements are anticipated to be less than 1 inch and ½-inch over 30 feet, respectively, for the proposed residential structures. The estimated magnitudes of static settlements are considered within tolerable limits for the proposed structures. As previously indicated in Section 5.5, areas of deep fill will require a waiting period of at least 2 months to achieve the tolerable settlement.

6.3.3 Allowable Bearing Value

Provided site grading is performed in accordance with the recommendations presented in this report, a bearing value of 1,800 pounds per square foot (psf) may be used for continuous footings and pad footings/beams having a minimum width of 12 inches and founded at a minimum depth of 12 inches below the lowest adjacent grade. This value may be increased by 200 psf and 550 psf for each additional foot in width and depth, respectively, up to a maximum value of 3,000 psf. Recommended allowable bearing values include both dead and live loads, and may be increased by one-third for wind and seismic forces.

6.3.4 Lateral Resistance

Provided site grading is performed in accordance with the recommendations presented in this report, a passive earth pressure of 260 pounds per square foot per foot of depth (psf/ft) up to a maximum value of 780 pounds per square foot (psf) may be used to determine lateral bearing for footings. This value may be increased by one-third when designing for wind and seismic forces. For footings facing descending slopes, this value should be reduced by 50%. A coefficient of friction of 0.31 times the dead load forces may also be used between concrete and the supporting soils to determine lateral sliding resistance. No increase in the coefficient of friction should be used when designing for wind and seismic forces.

The above values are based on footings placed directly against compacted fill or competent native soils. In the case where footing sides are formed, all backfill against the footings should be compacted to at least 90 percent of the laboratory standard.

6.3.5 Conventional Footings and Slabs on Grade (EI ≤ 20)

The recommendations in this section are applicable only where the expansion potential of the foundation soil expansion is classified as Very Low (EI ≤ 20). Exterior and interior building footings should be founded at a minimum depth of 12 inches below the lowest adjacent grade. All continuous footings should be reinforced with a minimum of two No. 4 bars, one top and one bottom. The structural engineer may require different reinforcement and should dictate if greater than the recommendations provided herein.

Interior isolated pad footings should be a minimum of 24 inches square and founded at minimum depths of 12 inches below the lowest adjacent final grade. Exterior isolated pad footings intended for support of patio covers or similar construction should be a minimum of 24 inches square and founded at a minimum depth of 12 inches below the lowest adjacent final grade.

Interior concrete slabs constructed on grade should be a minimum 4 inches thick and should be reinforced with 6-inch by 6-inch, W2 X W2 reinforcing wire mesh or No. 3 bars spaced 30 inches on center, each way. Care should be taken to ensure the placement of reinforcement at mid-slab height. The structural engineer may recommend a greater slab thickness and reinforcement based on proposed use and loading conditions and such recommendations should govern if greater than the recommendations presented herein.

Concrete floor slabs in areas to receive carpet, tile, or other moisture sensitive coverings should be underlain with a minimum of 10-mil moisture vapor retarder conforming to ASTM E 1745-11, Class A. The membrane should be properly lapped, sealed, and underlain with at least 2 inches of sand having a SE no less than 30. One inch of sand should be placed over the membrane to aid in the curing of the concrete. This vapor retarder system is anticipated to be suitable for most flooring finishes that can accommodate some vapor emissions. However, this system may emit more than 4 pounds of water per 1000 sq. ft. and therefore, may not be suitable for all flooring finishes. Additional steps should be taken if such vapor emission levels are too high for anticipated flooring finishes.

Special consideration should be given to slabs in areas to receive ceramic tile or other rigid, crack-sensitive floor coverings. Design and construction of such areas should mitigate hairline cracking as recommended by the structural engineer.

Garage floor slabs should have a minimum thickness of 4 inches and should be reinforced in a similar manner as living floor slabs. Garage floor slabs should also be poured separately from adjacent wall footings with a positive separation maintained with 3/8-inch minimum felt expansion joint materials, and provided with saw cuts or cold joints at a maximum spacing of 12 feet in each direction. Consideration should be given to providing a vapor retarder below the garage slab to mitigate the potential for effervescence on the slab surface.

Block-outs should be provided around interior columns to permit relative movement and mitigate distress to the floor slabs due to differential settlement that will occur between column footings and adjacent floor subgrade soils as loads are applied.

Prior to placing concrete, subgrade soils below slab-on-grade areas should be thoroughly moistened to provide a moisture content that is equal to or greater than 100% of the optimum moisture content to a depth of 12 inches.

6.3.6 Post-Tensioned Slabs on Grade (EI > 20)

Recommendations provided in this section on post-tensioned slab should be utilized where foundation soil exhibits an Expansion Index greater than 20.

Perimeter edge beams for the post-tensioned slab should have a minimum effective width of 12 inches and be founded at a minimum depth of 15 inches below the lowest adjacent final ground surface. Interior beams may be founded at a minimum depth of 12 inches below the tops of the finish floor slabs. If a post-tensioned mat is used, the outer 12 inches should be thickened to provide a minimum embedment of 8 inches below lowest grade, or to the depth of the underlying sand, whichever is deeper. The thickness of the floor slab/mat should be determined by the project structural engineer; however, we recommend a minimum slab thickness of 4 inches.

Concrete floor slabs in areas to receive carpet, tile, or other moisture sensitive coverings should be underlain with a minimum of 10-mil moisture vapor retarder conforming to ASTM E 1745-11, Class A. The membrane should be properly lapped, sealed, and underlain with at least 2 inches of sand having a SE no less than 30. One inch of sand should be placed over the membrane to aid in the curing of the concrete. This vapor retarder system is anticipated to be suitable for most flooring finishes that can accommodate some vapor emissions. However, this system may emit more than 4 pounds of

water per 1000 sq. ft. and therefore, may not be suitable for all flooring finishes. Additional steps should be taken if such vapor emission levels are too high for anticipated flooring finishes. Where a mat having a thickness of at least 8 inches is utilized, the sand may be reduced to 1 inch.

Prior to placing concrete, subgrade soils below slab-on-grade/mat areas should be thoroughly moistened to provide moisture contents that are at least 110 percent of the optimum moisture content to a depth of 12 inches.

Based on the guidelines provided in the "Design of Post-Tensioned Slabs-on-Ground" 3rd Edition by Post-Tensioning Institute, the e_m and y_m values for two expansive soil conditions are summarized in the table below:

TABLE 6.2
PTI Design Parameters

	Expansion Potential	
Parameter	**Low (20 < EI ≤ 50)**	**Medium (50 < EI ≤75)**
Edge Lift Moisture Variation Distance, e_m	4.6 feet	4.4 feet
Edge Lift, y_m	1.18 inches	1.78 inches
Center Lift Moisture Variation Distance, e_m	9.0 feet	8.5 feet
Center Lift, y_m	0.75 inches	1.19 inches

6.3.7 Foundation Setback

The bottom outer edge of foundations located adjacent a top of manufactured slope should be setback from the slope face a horizontal distance of at least ⅓ the height of the slope. The horizontal distance should not be less than 7 feet but need not exceed 40 feet. The above setback may be accomplished using deepened footings or caissons below the foundation if needed. If caissons are required, this office should provide specific recommendations.

Buildings adjacent the toe of a manufactured slope should be set back a horizontal distance equal to one-half the vertical height of the slope. The minimum and maximum clearances are 5 feet and 15 feet, respectively.

The bottom outer edge of foundations located adjacent a top of an existing slope should be setback from the slope face a horizontal distance of at least ⅔ the height of the slope. The horizontal distance should not be less than 7 feet.

6.3.8 Foundation Observations

Foundation excavation should be observed by the project geotechnical consultant to verify that they have been excavated into competent bearing soils and to the minimum embedment recommended above. These observations should be performed prior to placement of forms or reinforcement. The excavations should be trimmed neat, level and square. Loose, sloughed or moisture-softened materials and debris should be removed prior to placing concrete.

6.4 RETAINING AND SCREENING WALLS

6.4.1 General

The following recommendations are provided for preliminary design purpose. Final retaining wall designs specific to the site development should be provided to us for review once completed. The structural engineer and architect should provide recommendations for sealing at all joints and applying moisture-proofing material on the back of the walls.

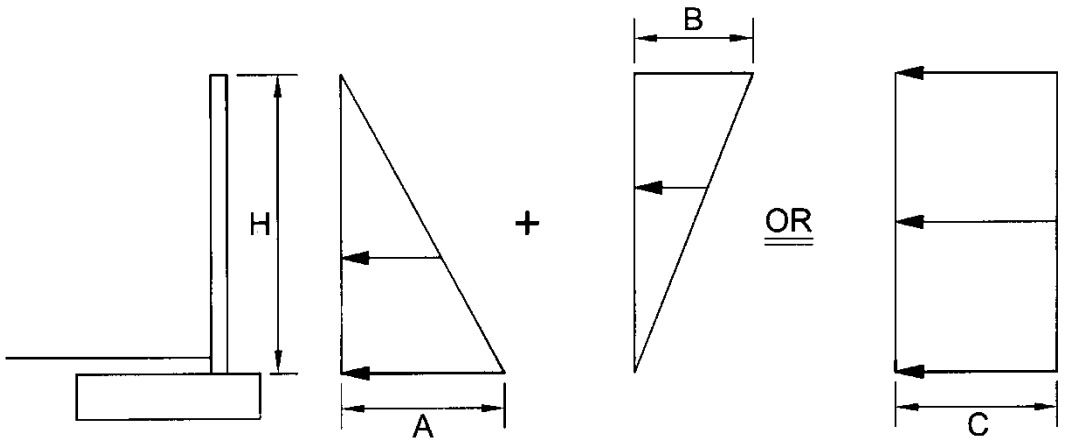
6.4.2 Allowable Bearing Value and Lateral Resistance

Retaining and freestanding walls may utilize a bearing value of 1,800 pounds per square foot (psf) for continuous and isolated footings founded at a minimum depth of 12 inches below the lowest adjacent grade and having a minimum width of 12 inches and 24 inches, respectively. This minimum bearing may also apply to continuous footings having a minimum width of 8 inches and minimum depth of 18 inches below lowest adjacent grade. The above bearing value may be increased by 200 psf and 550 psf for each additional foot in width and depth, respectively, up to a maximum value of 4,000 psf. Recommended allowable bearing values include both dead and live loads, and may be increased by one-third for wind and seismic forces.

A passive earth pressure of 210 pounds per square foot per foot of depth up to a maximum value of 1,050 pounds per square foot may be used to determine lateral bearing for footings. This value may be increased by one-third when designing for wind and seismic forces and should be reduced by 50 percent for walls that have a descending slope in front of the walls. A coefficient of friction of 0.31 times the dead load forces may also be used between concrete and the supporting soils to determine lateral sliding resistance. No increase in the coefficient of friction should be used when designing for wind and seismic forces. The coefficient of friction should not be applied to portions of the footing in front of keyways used for passive resistance.

The above values are based on footings placed directly against properly compacted fill. In the case where footing sides are formed, all backfill against the footings should be compacted to at least 90 percent of the laboratory standard.

6.4.3 Earth Pressures



Static and seismic earth pressures for active (unrestrained) and at-rest (restrained) conditions are provided in Table 6.3. The active values are given for both level and 2:1 (H:V) backfill conditions, whereas the at-rest values are only for level backfill condition. The seismic earth pressures provided herein are based on the method provided by Seed & Whitman (1970) for active state, and Wood (1973) for at-rest condition. Both these approaches were employed using peak ground acceleration of 0.55g for a 10% probability of exceedance in 50 years. As indicated in Section 1803.5.12 of the 2016 CBC, retaining walls supporting 6 feet of backfill or less are not required to be designed for seismic earth pressures.

The values provided in the following table are based on using backfill consisting of onsite materials having an Expansion Index of 50 or less. If import soil is used for retaining wall backfill, the earth pressures should be re-evaluated by the geotechnical consultant based on the properties of the import material. Import source(s) should be indicated to the geotechnical consultant prior to hauling the materials to the site so that appropriate testing and evaluation of the fill material can be performed in advance. Backfill should be placed within a 1:1 plane projected up from the base of the wall stem. In

addition, the values are based on drained backfill conditions and do not consider hydrostatic pressure. Furthermore, retaining walls should be designed to support adjacent surcharge loads imposed by other nearby footings or traffic loads in addition to the earth pressure.

TABLE 6.3
EARTH PRESSURES

Pressure Diagram

Pressure Values
Walls Up to 10 Feet in Height

Value	Active (Unrestrained)		At-rest (Restrained)
	Level	2H:1V Slope	Level
A	43H	78H	70H
B	17H	17H	30H
C	30H	48H	50H

Note: H is in feet and resulting pressure is in psf. Design may utilize either the sum of the static component and the seismic component force diagrams or the total force diagram above. SEAOSC has suggested using a load factor of 1.7 for the static component and 1.0 for the seismic component. The actual load factors should be determined by the structural engineer.

6.4.4 Drainage and Moisture-Proofing

Retaining walls should be constructed with a perforated pipe and gravel subdrain to prevent entrapment of water in the backfill. The perforated pipe should consist of 4-inch-diameter, ABS SDR-35 or PVC Schedule 40 with the perforations laid down. The pipe should be embedded in ¾- to 1½-inch open-graded gravel wrapped in filter fabric. The gravel should be at least one foot wide and

extend at least one foot up the wall above the footing and drainage outlet. Drainage gravel and piping should not be placed below outlets and weepholes. Filter fabric should consist of Mirafi 140N, or equal. Outlet pipes should be directed to positive drainage devices.

The use of weepholes may be considered in locations where aesthetic issues from potential nuisance water are not a concern. Weepholes should be 2 inches in diameter and provided at least every 6 feet on center. Where weepholes are used, perforated pipe may be omitted from the gravel subdrain.

Retaining walls supporting backfill should also be coated with a moisture-proofing compound or covered with such material to inhibit infiltration of moisture through the walls. Moisture-proofing material should cover any portion of the back of wall that will be in contact with soil and should lap over and onto the top of footing. A drainage panel should be provided between the soil backfill and water proofing. The panel should extend from the top of the backdrain gravel up to within 12 inches of finish grade. The top of footing should be finished smooth with a trowel to inhibit the infiltration of water through the wall. The project structural engineer should provide specific recommendations for moisture-proofing, water stops, and joint details.

6.4.5 Foundation Setback

Retaining wall foundations constructed adjacent descending slopes should be deepened such that the outer bottom face of the footing is positioned at least 7 feet horizontally from the slope face.

6.4.6 Footing Reinforcement and Jointing

All continuous footings should be reinforced with a minimum of four No. 4 bars, two top and two bottom. The structural engineer may require different reinforcement and should dictate if greater than the recommendations provided herein. Where recommended removals are limited due to space restrictions, greater reinforcement may be recommended. Specific recommendations should be provided by the geotechnical consultant during grading based on as-built conditions exposed in the field.

Masonry walls should be provided with cold joints spaced about 20 feet along the wall. The joint should penetrate the full thickness of the wall but should not continue through the footing.

6.4.7 Footing Observations

Footing excavations should be observed by the project geotechnical consultant to verify that they have been excavated into competent bearing soils and to the minimum embedment recommended herein. These observations should be performed prior to placement of forms or reinforcement. The excavations should be trimmed neat, level and square. Loose, sloughed or moisture-softened materials and debris should be removed prior to placing concrete.

6.4.8 Retaining Wall Backfill

Most site soils in the project area are considered suitable as compacted backfill. Onsite soils used for wall backfill should consist of material with an Expansion Index (EI) not exceeding 50. The material should be placed behind the wall and extend laterally to a 1 to 1 plane projected up from the base of the wall footing. Beyond the 1 to 1 plane, the backfill may consist of general onsite soils or imported soils. The project geotechnical consultant should approve the backfill used for retaining walls. Wall

backfill should be thoroughly moistened to provide moisture contents slightly over optimum moisture content; placed in lifts no greater than 12 inches in thickness, and then mechanically compacted with appropriate equipment to at least 90 percent of the laboratory standard. Hand-operated compaction equipment should be used to compact the backfill placed immediately adjacent the wall to avoid damage to the wall. Flooding or jetting of backfill material is not recommended.

6.5 CONCRETE MIX DESIGN

Laboratory testing of on-site soils indicates negligible soluble sulfate content. We recommend following the procedures provided in ACI 318, Section 4.3, Table 4.3.1 for **negligible** sulfate exposure. Upon completion of rough grading, an evaluation of as-graded conditions and further laboratory testing should be completed for the site to confirm or modify the recommendations provided in this section.

6.6 EXTERIOR FLATWORK

Portions of the existing site soils are generally expansive and will tend to cause heave in exterior flatwork. To help mitigate adverse effects of expansive soils, we are providing the following minimum recommendations. Even with implementation of these recommendations, flatwork may tend to move and crack.

Exterior flatwork should be a minimum 4 inches thick. Cold joints or saw cuts should be provided at least every 7 feet in each direction. Flatwork more than 7 feet in width across the minimum dimension should be reinforced with 6" by 6", W2.9xW2.9 welded wire mesh or No 3 bars spaced 24 inches center to center in both directions. Cold joints should be keyed or provided with dowels spaced 24 inches on center. Flatwork that meets the structure at points of entry should be doweled into the footing or grade beam of the structure. Special jointing detail should be provided in areas of block-outs, notches, or other irregularities to avoid cracking at points of high stress. Subgrade soils below flatwork should be thoroughly moistened to at least 120 percent of optimum moisture content to a depth of 12 inches. Moistening should be accomplished by lightly spraying the area over a period of a few days just prior to pouring concrete.

Drainage from flatwork areas should be directed to local area drains or other appropriate collection devices designed to carry runoff water to the street or other approved drainage structures. The concrete flatwork should also be sloped away from building foundations and masonry walls at a minimum gradient of 1%.

The geotechnical consultant should observe and verify the density and moisture content of subgrade soils prior to pouring concrete to verify the recommended pre-moistening recommendations have been met.

6.7 POST GRADING CONSIDERATIONS

6.7.1 Site Drainage and Irrigation

Positive drainage devices, such as sloping concrete flatwork, graded swales or area drains, should be provided around the new construction to collect and direct all surface water to suitable discharge areas. No rain or excess water should be directed toward or allowed to pond against structures such as walls, foundations, flatwork, etc. The ground immediately adjacent to foundations should be provided with positive drainage away from the structures in accordance with 2016 CBC, Section 1804.4. Based on soil and climatic factors, the ground slope adjacent structures may be reduced to 2%.

Excessive irrigation water can be detrimental to the performance of the proposed site development. Water applied in excess of the needs of vegetation will tend to percolate into the ground. Such percolation can lead to nuisance seepage and shallow perched groundwater. Seepage can form on slope faces, on the faces of retaining walls, in streets, or other low-lying areas. These conditions could lead to adverse effects such as the formation of stagnant water that breeds insects, distress or damage of trees, surface erosion, slope instability, discoloration and salt buildup on wall faces, and premature failure of pavement. Excessive watering can also lead to elevated vapor emissions within structures that can damage flooring finishes or lead to mold growth inside the home.

Key factors that can help mitigate the potential for adverse effects of overwatering include the judicious use of water for irrigation, use of irrigation systems that are appropriate for the type of vegetation and geometric configuration of the planted area, the use of soil amendments to enhance moisture retention, use of low-water demand vegetation, regular use of appropriate fertilizers, and seasonal adjustments of irrigation systems to match the water requirements of vegetation. Specific recommendations should be provided by a landscape architect or other knowledgeable professional.

6.7.2 Utility Trenches

Trench excavations should be constructed in accordance with the recommendations contained in Section 6.1.17 of this report. Trench excavations must also conform to the requirements of Cal/ OSHA.

Trench backfill materials and compaction criteria should conform to the requirements of the local municipalities. As a minimum, utility trench backfill should be compacted to at least 90 percent of the laboratory standard. Trench backfill should be moistened to slightly over the optimum moisture content, placed in lifts no greater than 12 inches in thickness, and then mechanically compacted with appropriate equipment to at least 90 percent of the laboratory standard. The project geotechnical consultant should perform density testing, along with probing, to test compaction. Site conditions are generally not suitable for jetting of trench backfill and jetting should not be completed without prior approval from the project geotechnical consultant.

Within shallow trenches (less than 18 inches deep) where pipes may be damaged by heavy compaction equipment, imported clean sand having a SE of 30 or greater may be utilized. The sand should be placed in the trench, thoroughly moistened, and then compacted with a vibratory compactor. For utility trenches located below a 1:1 (H:V) plane projecting downward from the outside edge of the adjacent footing base or crossing footing trenches, concrete or slurry should be used as trench backfill.

Clayey soils present at the site will tend to cause water to collect in trench shading. This water could migrate along the trenches and below homes where excessive moisture conditions could be created. To mitigate this condition, we recommend the sand bedding and shading be omitted for a trench length of 2 feet just outside the house where the trench enters below the home. The bedding and shading should consist of soils similar to the general trench backfill soils. As an alternate, the trench may be backfilled with 2-sack slurry for a trench length of 2 feet just outside the house provide the slurry fully encapsulates the utility.

As previously discussed in Section 5.5, portions of the site will be subject to significant long-term settlement. Such settlement may impact underground utilities where they cross drainages with fills greater than 50 feet by placing them in tension as the ground settles. If proposed underground improvements can be compromised by this effect, mitigating steps will be required to accommodate this long-term settlement. Such steps may include jogs in the alignment, flexible joints, or slip joints.

6.8 SLOPE MAINTENANCE

The long-term performance and stability of slopes can be greatly affected by maintenance. Initially, slopes should be provided with erosion resistance in the form of an herbaceous plant material, jute matting, polymer coating, or other suitable method as recommended by the landscape architect. Slopes should also be planted with deep-rooting, drought-tolerant, woody vegetation material as recommended by the landscape architect. The initial protection should be maintained until the woody material has become fully mature. Areas of slopes where vegetation becomes particularly distressed or dies should be replaced promptly. Watering of slopes should make judicious use of water by providing only that amount required to support the vegetation and adjusting the watering seasonally. Over watering must be avoided. Excessive drying of the soils is also detrimental to long-term slope performance and stability. The moisture content of soils should be maintained at a relatively uniform level. Rodent activity should be monitored and kept to a minimum. Excessive rodent burrowing can be detrimental to long-term slope performance and stability and should be repaired promptly. Drainage devices, such as V-ditches and backdrain outlet pipes installed on the slope face, should be periodically inspected to confirm they are clear and functional. Any accumulated debris should be removed promptly.

6.9 PRELIMINARY PAVEMENT DESIGN

6.9.1 Preliminary Pavement Structural Sections

Based on the soil conditions present at the site and estimated traffic indices, preliminary pavement sections are provided in the tables below. Based on a preliminary estimate, an "R-value" of 20 was used for this preliminary pavement design. The sections provided below are for planning purposes only and should be re-evaluated subsequent to site grading. Final pavement sections should be based on actual R-value testing of in-place soils and analysis of anticipated traffic.

TABLE 6.4
Preliminary Pavement Structural Sections

Location	Traffic Index	Asphalt Concrete (inches)	Aggregate Base (inches)
Primary Access Road	7.0	4.0	13.0
		5.0	11.0
Secondary Road	6.0	4.0	10.0
Secondary Road	5.0	4.0	7.0

6.9.1 Subgrade Preparation

Prior to placement of paving elements, subgrade soils should be moisture-conditioned to at least 110 percent of the optimum moisture content then compacted to at least 90 percent of the laboratory determined maximum dry density. Areas observed to pump or yield under vehicle traffic should be removed and replaced with firm and unyielding compacted soil or aggregate base materials.

6.9.2 Aggregate Base

Aggregate base should be moisture conditioned to slightly over the optimum moisture content, placed in lifts no greater than 6 inches in thickness, then compacted to at least 95 percent of the laboratory standard (ASTM D 1557). Aggregate base materials should be Class 2 Aggregate Base conforming to Section 26-1 of the 2010 Edition of the Caltrans Standard Specifications, Crushed Aggregate Base conforming to Section 200-2.2 of the 2015 Edition of the Standard Specifications for Public Works Construction (Greenbook) or Crushed Miscellaneous Base conforming to Section 200-2.4 of the Greenbook.

6.9.3 Asphaltic Concrete

Paving asphalt should be PG 64-10. Asphaltic concrete materials should conform to Section 203-6 of the Greenbook and construction should conform to Section 302 of the Greenbook.

6.10 PLAN REVIEW AND CONSTRUCTION SERVICES

We recommend ***Albus-Keefe & Associates, Inc*.** be engaged to review any future development plans, including grading plans, structural plans (foundation plans), and retaining wall plans, prior to construction. This is to verify that the assumptions of this report are valid and that the preliminary conclusions and recommendations contained in this report have been properly interpreted and are incorporated into the project plans and specifications. If we are not provided the opportunity to review these documents, we take no responsibility for misinterpretation of our preliminary conclusions and recommendations.

We recommend that a geotechnical consultant be retained to provide soil engineering services during construction of the project. These services are to observe compliance with the design, specifications or recommendations, and to allow design changes in the event that subsurface conditions differ from those anticipated prior to the start of construction.

If the project plans change significantly from the assumed development described herein, the project geotechnical consultant should review our preliminary design recommendations and their applicability to the revised construction. If conditions are encountered during construction that appear to be different than those indicated in this report or subsequent design reports, the project geotechnical consultant should be notified immediately. Design and construction revisions may be required.

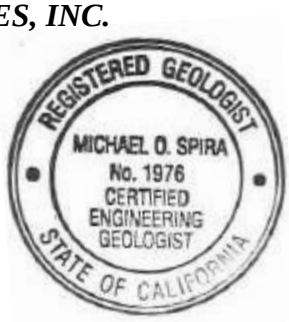
7.0 LIMITATIONS

This report is based on the proposed development and geotechnical data as described herein. The materials described herein and in other literature are believed representative of the total project area, and the conclusions contained in this report are presented on that basis. However, soil materials can vary in characteristics between points of exploration, both laterally and vertically, and those variations could affect the conclusions and recommendations contained herein. As such, observation and testing by a geotechnical consultant prior to and during the grading and construction phases of the project are essential to confirming the basis of this report.

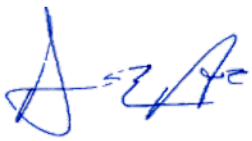
This report summarizes several geotechnical topics that should be beneficial for project planning and budgetary evaluations. The information presented herein is intended only for a preliminary feasibility evaluation and is not intended to satisfy the requirements of a site specific and detailed geotechnical investigation required for further planning, design and permitting.

This report has been prepared consistent with that level of care being provided by other professionals providing similar services at the same locale and time period. The contents of this report are professional opinions and as such, are not to be considered a guaranty or warranty.

This report should be reviewed and updated after a period of one year or if the site ownership or project concept changes from that described herein.



This report has been prepared for the exclusive use of the **Comstock Homes** to assist the project consultants in the planning and design of the proposed development. This report has not been prepared for use by parties or projects other than those named or described herein. This report may not contain sufficient information for other parties or other purposes.



Respectfully submitted,

ALBUS-KEEFE & ASSOCIATES, INC.

APPENDIX A

EXPLORATION LOGS
by Albus-Keefe & Associates Inc.

APPENDIX A-1

CURRENT INVESTIGATION

EXPLORATION LOG

Project:		Location:
Address:		Elevation:
Job Number:	Client:	Date:
Drill Method:	Driving Weight:	Logged By:

Depth (feet)	Lith-ology	Material Description	Water	Samples: Blows Per Foot	Samples: Core	Samples: Bulk	Laboratory Tests: Moisture Content (%)	Laboratory Tests: Dry Density (pcf)	Laboratory Tests: Other Lab Tests
		EXPLANATION							
		Solid lines separate geologic units and/or material types.							
		Dashed lines indicate unknown depth of geologic unit change or material type change.							
5		**Solid black rectangle** in Core column represents California Split Spoon sampler (2.5in ID, 3in OD).							
		Double triangle in core column represents SPT sampler.							
10		**Vertical Lines** in core column represents Shelby sampler.							
		Solid black rectangle in Bulk column respresents large bag sample.							
		Other Laboratory Tests:							
15		Max = Maximum Dry Density/Optimum Moisture Content							
		EI = Expansion Index							
		SO4 = Soluble Sulfate Content							
		DSR = Direct Shear, Remolded							
		DS = Direct Shear, Undisturbed							
		SA = Sieve Analysis (1" through #200 sieve)							
		Hydro = Particle Size Analysis (SA with Hydrometer)							
20		200 = Percent Passing #200 Sieve							
		Consol = Consolidation							
		SE = Sand Equivalent							
		Rval = R-Value							
		ATT = Atterberg Limits							

EXPLORATION LOG

Project:		Location: B-1
Address: 787 Poindexter Ave, Moorpark, CA 93021		Elevation: 513.3
Job Number: 2677.00	Client: Comstock, Crosser & Assoc.	Date: 9/18/2018
Drill Method: Hollow-Stem Auger	Driving Weight: 140 lbs / 30 in	Logged By: SB

Depth (feet)	Lith-ology	Material Description	Water	Samples: Blows Per Foot	Samples: Core	Samples: Bulk	Laboratory Tests: Moisture Content (%)	Laboratory Tests: Dry Density (pcf)	Laboratory Tests: Other Lab Tests
		COLLUVIUM (Qcol) Silty Sand / Sandy Silt (SM/ML): Dark brown to brown, dry, fine to medium grained sand							
		Silty Sand / Clayey Sand (SM/SC): Dark brown, dry to damp, medium dense, fine grained sand, trace gravel, porous, rootlets present, trace medium and coarse grained sand		17	■	■	4.6	93.5	
5		@ 5 ft, disturbed, rings damaged, blow counts affected, slightly less pores		37	■		5.8	116.5	
10		@ 10 ft, brown to reddish brown, damp, root hairs present		16	■		6.1	103.2	
15		@ 15 ft, brown to dark brown, trace pores		16	■		7.5	114.9	
		Clayey Sand (SC): Yellowish brown, damp to moist, medium dense, fine grained sand, trace gravel, porous, slightly blocky							
20				16	■		11.4	107.5	Consol

	7.0-13.5	CL/SC	Sandy Clay / Clayey Sand: Yellowish brown, damp to moist, soft to medium stiff / loose, fine grained sand, some pores. Gradually becomes sandier with depth.
			Possible Saugus Formation (Qs)?:
	13.5-14.0		Claystone with Sand: Olive gray, moist to very moist, stiff, fine grained sand, slight blocky ped development with clay films on ped surfaces, trace pores.
			Total Depth: 14.0 feet No groundwater Backfilled w/spoils

Trench Number	Depth (Feet)	U.S.C.S. Symbol	Field Description
T-30			
			Colluvium (Qcol):
	0-6.0	CL	Sandy Clay: Dark brown, damp to moist, soft to medium stiff, fine grained sand, trace gravel, porous.
	6.0-13.0	CL/SC	Sandy Clay & Clayey Sand: Mottled brown and gray, damp, soft to medium stiff / loose, fine grained sand, porous. @ 9 ft, becomes dark brown, medium stiff / medium dense, blocky ped development with clay films on ped surfaces, still porous.
			Saugus Formation (Qs):
	13.0-14.5		Clayey Sandstone: Mottled brown and grayish brown, moist to very moist, medium dense, fine grained sand, trace pores.
			Total Depth: 14.5 feet No groundwater Backfilled w/spoils

DESCRIPTIVE LOG OF TRENCH EXCAVATION

Trench Number	Depth (Feet)	U.S.C.S. Symbol	Field Description
T-31			
			Colluvium (Qcol):
	0-4.0	CL	Sandy Clay: Dark brown, damp, soft to medium stiff, fine grained sand, some gravel, porous.
	4.0-8.0	CL	Sandy Clay: Strong brown, damp to moist, soft to medium stiff, fine grained sand, some gravel, blocky ped development with clay films on ped surfaces.
			@ 7.0 ft, increased gravel, trace cobbles up to 6 inches in size.
			Possible Saugus Formation (Qs)?:
	8.0-12.0		Clayey Sandstone: Yellowish brown, moist, medium dense, fine to medium grained sand, some pores and rootlets.
			Total Depth: 12.0 feet No groundwater Backfilled w/spoils

DESCRIPTIVE LOG OF TRENCH EXCAVATION

Trench Number	Depth (Feet)	U.S.C.S. Symbol	Field Description
T-32			
			Colluvium (Qcol):
	0-3.0	CL	Sandy Clay: Dark brown, dry to damp, soft to medium stiff, fine grained sand, porous.
			Possible Saugus Formation (Qs)?:
	4.0-8.0		Sandy Claystone: Reddish brown, damp, medium stiff, fine grained sand, blocky ped development with clay films on ped surfaces, porous.
	8.0-12.0		Clayey Sandstone: Light reddish brown, damp, loose to medium dense, fine to medium grained sand, some pores. Gradually becomes sandier with depth. Occasional thin silt layers with abundant old root channels and manganese oxide staining.
			Total Depth: 12.0 feet No groundwater Backfilled w/spoils

Trench Number	Depth (Feet)	U.S.C.S. Symbol	Field Description
T-33			
			Colluvium (Qcol):
	0-6.5	CL	Sandy Clay: Dark brown, damp, soft to medium stiff, fine grained sand, some gravel, porous. @ 6.0 ft, increased gravel, trace cobbles up to 6 inches in size.
			Saugus Formation (Qs):
	6.5-8.0		Clayey Sandstone: Mottled reddish brown and gray, moist, medium dense, fine to medium grained sand, some pores. Upper 1 to 2 feet is weathered and porous.
			Total Depth: 8.0 feet No groundwater Backfilled w/spoils

T-34			
			Top Soil (No Map Symbol):
	0-2.5	CL	Sandy Clay: Dark brown, dry to damp, soft to medium stiff, fine grained sand, trace gravel, blocky ped development with clay films on ped surfaces, porous.
			Saugus Formation (Qs):
	2.5-4.0		Sandy Claystone: Light reddish brown, moist, medium stiff to stiff, fine grained sand, abundant carbonate filaments, some pores, weathered.
	4.0-7.0		Silty Sandstone: Light reddish brown, damp to moist, medium dense to dense, fine to medium grained sand, trace clay, some krotovinas in upper 12 inches.
			@ 5ft, increased silt.
			Total Depth: 7.0 feet No groundwater Backfilled w/spoils

Trench Number	Depth (Feet)	U.S.C.S. Symbol	Field Description
T-35			
			Top Soil (No Map Symbol):
	0-2.5	CL	Sandy Clay: Dark brown, dry to damp, soft to medium stiff, fine grained sand, trace gravel, blocky ped development with clay films on ped surfaces, porous, carbonate filaments along base.
			Saugus Formation (Qs):
	2.5-5.0		Silty Sandstone with Clay: Reddish brown, moist, medium dense, fine grained sand, some pores and krotovinas, weathered.
	5.0-6.0		Silty Sandstone / Sandy Siltstone: Light reddish brown, moist, medium dense / stiff, fine grained sand, trace pores.
			Total Depth: 6.0 feet No groundwater Backfilled w/spoils
